Objective: Our aim was to identify causes of recurrent spontaneous abortion among Sudanese women population. Method: Observational study was carried out in Omdurman Maternal Hospital, Sudan between June 2013 to Aug. 2014. The study enrolled 100 women aged 17 to 45 years with history of at least three or more of recurrent spontaneous abortion less than 20 weeks gestation. Questionnaire and direct interview were used to collect information and detailed clinical history, thorough clinical examination and investigated with all patients of pre-decided laboratory tests and special tests wherever relevant and possible, were done then the causes of recurrent spontaneous abortion were evaluated among all cause which enrolled in this study. Results: Out of 100 cases 24% were diagnosed, while 76% cases remained unexplained. Inherited thrombophilia were detected in 14%, Anatomical causes was detected in 1% cases, 6% had Endocrine etiology comprising of diabetes mellitus and Infective cause in 3% of women. Conclusion: we conclude that from our study the majority of cases of recurrent spontaneous abortion remain unexplained and inherited thrombophilia causes account for majority causes in SRA.

Keywords: Sudanese Pregnant Women, Recurrent spontaneous abortion

1. Introduction

Recurrent Spontaneous abortion is defined as consecutive pregnancy loss before 20 weeks gestation or fetal weight of 500 g or less (¹). There are numerous factors that may cause (RSA), but the underlying problem often remains undetected. The known causes of RSA include chromosomal and metabolic abnormalities, uterine anomalies, and immunologic factors (²). Still now the etiology of recurrent pregnancy loss (RPL) remains unclear, but it may be related to a possible genetic predisposition together with involvement of environmental factors (³). Historically, recurrent miscarriage has been attributed to either genetic, structural, infective, endocrine, immune, or unexplained causes. Thrombophilic disorders are thought to play a part in the cause of recurrent pregnancy loss, which widens the scope of investigations and management options for recurrent miscarriage. Many syndromes associated with recurrent fetal loss include anatomic anomalies, endocrine/hormonal abnormalities, genetic, chromosomal abnormalities, and blood coagulation protein/platelet defects (⁴). The risk of (RSA) after two consecutive losses is 17% to 25% and the risk of miscarrying fourth pregnancy loss after three consecutive losses is between 25% and 46% (⁵). Clinical studies indicate that the risk of another miscarriage after three consecutive pregnancy losses is 30-45%. Furthermore, without any workup or treatment, the chance of a successful live birth in a couple with a history of RPL and no previous live birth is 55-60%. If the couple has a history of RPL and has had at least one previous normal pregnancy, the chance of a subsequent live birth is 70% (⁶). Also there are many cause of RSA related to environmental factor like cigarette smoking has been suggested to have an adverse effect on trophoblast function and is linked to an increased risk of sporadic pregnancy loss. Also obesity has been shown to be associated with an increased risk of RSA in women who conceive naturally. Other life-style habits such as cocaine use, alcohol consumption (3 to 5 drinks per week), and increased caffeine consumption (> 3 cups of coffee) have been associated with risk of pregnancy loss (⁷).

2. Materials and Methods

Between June 2013 to Aug 2014, 100 women, 17– 45 years of age, with at least 3 recurrent spontaneous consecutive abortions were referred to the Omdurman Maternity Hospital in Sudan. The study group data collected using structure questionnaire and direct interview to collect information about age, parity, medical and obstetric history, smoking, family medical and obstetric history, residency and history of infections. Clinical examination and investigated with all patients of pre-decided laboratory tests and special tests wherever relevant and possible, were done then the causes of recurrent spontaneous abortion were evaluated among all cause which enrolled in this study. Then data were entered and analyzed by SPSS programme (version: 17.0). All demographic data of the study population were presented as mean ± SD in the text and Odds Ratio was used for detecting the power of relationship between the determinant and the outcome and 95% confidence interval was calculated.

Ethics:

Ethical consent was obtained from ethical committee of Hospital of Omdurman Maternity Hospital (Sudan).

3. Results

Out of 100 cases 24% were diagnosed, while 76% cases remained unexplained. Inherited thrombophilia were detected in 14%, Anatomical causes was detected in 1%
cases, 6% had Endocrine etiology comprising of diabetes mellitus and Infective cause in 3% of women.

4. Discussion

Recurrent spontaneous abortion (RSA) is a worldwide clinical and stressful problem that has been studied tremendously but the causes and treatment have not been fully resolved. And also RSA is the most common complication of pregnancy, is the spontaneous loss of a pregnancy before the fetus has reached viability. Improvement of pregnancy outcome is considered as an important area of action for those concerned with the improvement of women’s health and pregnancy outcome. In the present study out of 100 cases 24% were diagnosed, while 76% cases remained unexplained. Inherited thrombophilia were detected in 14%. Anatomical causes was detected in 1% cases, 6% had Endocrine etiology comprising of diabetes mellitus and Infective cause in 3% of women. (Table I &Fig I). Endocrin etiology was found in 6% patients. This result was compared with Saito, et.al study who reported the rate of endocrinical causes in 6.9% cases among Japanese women with recurrent abortion women (8). Also this study was agreed with another study done by Pradhan, et.al among recurrent pregnancy loss women in rural population in Maharashtra in Indian population (9). The 3% of infection by toxoplasmosis was compare by study done by Elsheikha, reported that the seroprevalence of Toxoplasma gondii antibodies in pregnant women varies from the 6.1 to 75.2 percent based on the geographical region (10). However, the etiologic mechanisms linking specific organisms to either isolated or recurrent pregnancy loss remain unclear and must certainly differ among infectious organisms. (11, 12, 13). The result of inherited thrombophilia 14% disagree with study done by Brenner, et.al., identified thrombophilia as a principal cause in more than 40% of women affected by RPL (14). Anatomic abnormalities account about 1% among cases of our study differ from the study done by Jaslow, et.al., about 16 - 18% among women with two versus three or more recurrent pregnancy losses (15). Also compare by another study by Foka, et al. Found that 19% of miscarriage patients (15 of 80) carried inherited thrombophilia (16). Other studies done by Asaad and Fathelrahman, among Sudanese women fail to establish the relationship between inherited thrombophilia, Age, BO and ethnic with the spontaneous recurrent abortion (17, 18). The anatomical etiological factor showed the lowest cause among cases in our study. As findings of the current study seems to indicate limited explained of the most cases a pronounced Special concern should be paid for couples with recurrent spontaneous abortion women should be tested for more immunologic, environmental factor, genetics and other physical abnormalities in women reproductive system to find more risk factor among these women.

5. Conclusion

We conclude that from our study the majority of cases of recurrent spontaneous abortion remain unexplained and inherited thrombophilia causes account for majority causes among those women. As a finding of the current study seems to indicate 76% cases remained unexplained. Special concern should be paid for couples with recurrent spontaneous abortion should be tested for more immunologic, environmental factor, genetics and other physical abnormalities in women reproductive system to find more risk factor among these women.

6. Acknowledgments

We are grateful for the all women for participating in our study. And special thank to the staff of Omdurman Maternity Hospital in Sudan.

7. Conflict of Interest

I declare that there is no conflict of interest with any others but the authors.
