**Abstract:** *In developing countries, remote areas and particularly in Africa, water pumping is increasingly used to gain access to water. Submerged electric pumps face two major operating problems: variations in internal parameters and external disturbances. This article proposes an optimal control strategy for a photovoltaic pumping system, based on the dual use of fuzzy logic to allow access to water in quantity. The complete system, operating over the sun is modelled and simulated on Matlab/Simulink including a photovoltaic generator, an adaptation stage (chopper-inverter) and a submerged electric pump. The switch (IGBT) of the booster chopper is controlled by a fuzzy controller that regularly adjusts the duty cycle according to the climatic conditions and ensures the operation of the submerged electric pump at the maximum power point. Adaptive control by reference model of the electropump's speed based on fuzzy logic is used and presents a better efficiency.*

**Keywords:** Adaptive control, Submersible pump, Fuzzy logic, MPPT, Photovoltaic energy

## 1. Introduction

The United Nations in its latest report on the development of water resources estimates that 30% of the world's population still does not have access to safe drinking water at home [1]. According to the World Health Organization, 884 million people worldwide do not have a basic service of access to drinking water. Of the 884 million people who do not have access to safe drinking water, 263 million have to travel thirty minutes round trip to the nearest water point. 423 million people drink well or spring water that is not protected from contamination. As many as 159 million people collect their drinking water in a river, lake or irrigation canal, at the risk of contamination by chemicals and feces [2].

In Cameroon, out of nearly 24 million inhabitants, about 8 million 890,000 do not have access to a drinking water service. Only 52.3% of the population at the national level uses an improved (modern) sanitation facility. Faced with these alarming figures, regular handwashing to protect against COVID-19 and other infectious diseases is not possible in the absence of water.

One of the most effective solutions that would ensure access to water in quantity, regardless of the location, is the use of photovoltaic conversion of solar energy to operate water pumps. Solar-run photovoltaic pumping systems typically consist of a photovoltaic generator (GPV), energy converters, and an electric pump.

The main disadvantage to the use of such a system continues to be their high initial cost and low water yield. The investigations carried out to optimize the operation of this

system in recent years are grouped into two categories. The first concerns those who seek to optimize the operation of the GPV through the search for the maximum power point (MPPT) via different algorithms and static converters [3], [4], [5], [6]. The second category groups those who seek to optimize the electropump's control [7], [8], [9].

This work fits into both categories of research, through the coupled use of two fuzzy regulators. The first regulator allows the photovoltaic generator to provide the maximum power to the submerged electric pump and the second regulator, through an adaptive control by reference model allows to optimize the rotation of the speed submerged electric pump's motor regardless of external disturbances.

This article in its joints, first presents the title Material and Methods which illustrate in detail the Simulink model of the GPV, the adaptation stage (chopper and inverter) integrating the technique of locking the duty cycle through the MPPT-FL control and then the submerged electric pump's Simulink model. Then a presentation discussed the results obtained and we finish with a conclusion.

## 2. Equipment and methods

### 2.1 Equipment

As part of this work, we used an acer computer Intel (R) dual core processor, 2.3 GHz, Matlab R2018a software, a Helios H750 brand photovoltaic module to power the submerged electric pump and an experimental database of climate parameters recorded on January 11, 2021 (from 9am to 4pm) at the University of Ngaoundere in Cameroon.

2.2 Methods

2.2.1 Photovoltaic generator

We use in this article the basic structure of a one-diode photovoltaic cell. The equivalent circuit of the GPV and the different equations leading to equation (1) are provided in [10].

$$I_{pv} = I_{cc} - I_c \left[ \exp \left( \frac{V_{pv} + R_s I_{pv}}{V_t \times N_{cs}} \right) - 1 \right] \quad (1)$$

The block diagram in Figure 1 shows the Simulink model of the PV module (a) and the GPV (b), based on equation (1) whose parameters are solved by the Newton-Raphson method in the Matfile.

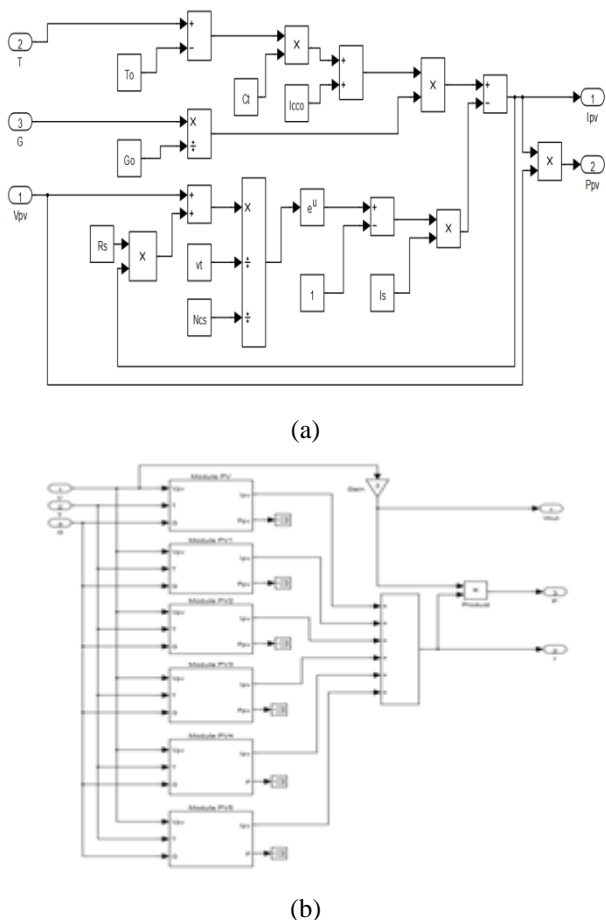

Figure 1: Simulink model of the module and PV generator

For the simulation of the GPV, we associate in series 3 rows of 6 PV modules in parallel ( $N_p = 6$ ,  $N_s = 3$ ) as shown in Figure 1.b, for an available power of 1559.09 W under 24.06 A and 64.8 V and allowing the pump to supply 1.3 l / s under 6 bar.

2.2.2 Adaptation stage of the photovoltaic generator

2.2.2.1 DC-DC Converter: Boost Chopper

The main role of the Simulink model of the booster chopper shown in Figure 2, is to change the voltage from a low value

to a higher value by varying the cyclic ratio (d) in the following relationships (2) and (3).

$$V_{out} = \frac{V_{in}}{1-d} \quad (2)$$

$$I_{out} = (1-d)I_{in} \quad (3)$$

$V_{in}$  et  $I_{in}$  represent respectively the voltage and current at the input of the chopper and  $V_{out}$ ,  $I_{out}$  represent the output.

The values of the inductance L and the capacity C of the converter are calculated as follows:

$$L = d \frac{V_{in}}{f \cdot \Delta I} \quad (4)$$

$$C = d \frac{I_{out}}{f \cdot \Delta V} \quad (5)$$

With f as frequency and  $\Delta I$ ,  $\Delta V$  the ripple size of the current and voltage respectively. Using the maximum values of current and voltage, the numerical application of relationships (3) and (4) give 30  $\mu$ H and 470  $\mu$ F respectively.

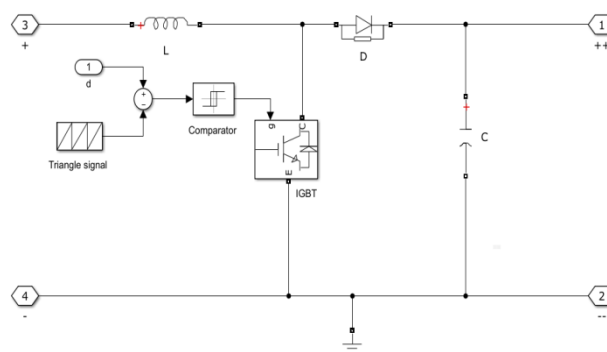

Figure 2: Simulink model of the booster chopper.

At the input of the control signal, a comparator makes it possible to make the analysis between a triangular signal of frequency 100 kHz and the cyclic ratio provided by the MPPT-fuzzy control algorithm.

2.2.2.2 Implementation of the MPPT-Fuzzy control algorithm

MPPT allows the GPV to operate at maximum power despite variations in sunlight, temperature and load [11], [12], [13]. We find in the literature about twenty methods based on the research of the PPM PV modules. Control by fuzzy logic offers the advantage of being robust, efficient and works at PPM without oscillation [3], [5]. There are different ways to implement a fuzzy regulator but in general the presentation adopted is divided into three stages: fuzzification, inference and defuzzification (Figure 3).

Figure 3: Block diagram of the algorithm based on fuzzy logic

The fuzzification step allows the conversion of input variables into fuzzy variables. In our case, we have two entries: the error (err) and the variation of the error (derr) defined by the following relationships (6) and (7).

$$err = \frac{P_{pv}(k) - P_{pv}(k-1)}{V_{pv}(k) - V_{pv}(k-1)} \quad (6)$$

$$derr(k) = err(k) - err(k-1) \quad (7)$$

Where  $P_{pv}(k)$  and  $V_{pv}(k)$  are respectively the power and instantaneous voltage of the GPV. These quantities are assigned language variables: LN (Large Negative), SN (Small Negative), ZE (Zero), SP (Small Positive) and LP (Large Positive). The different inference rules that govern the operation of the regulator are given in Table 1 and the membership functions of the inputs and outputs used are given in [14].

Table 1: Inference Rules

$derr \rightarrow$	LN	SN	ZE	SP	LP
$err \downarrow$					
LN	ZE	ZE	LP	LP	LP
SN	ZE	ZE	SP	SP	PP
ZE	SP	ZE	ZE	ZE	SN
SP	SN	SN	SN	ZE	ZE
LP	LN	LN	LN	ZE	ZE

We take as an example of the control rules of table 1: "If err is LP and derr is ZE Then d is LN". This means that: "If the operating point is far from the point of maximum power (PPM) to the left side and the change in the slope of the X curve is about Zero; So decrease the cyclical ratio (d) widely". Finally, in defuzzification, we convert the fuzzy output subsets into a numerical value by the centre gravity method and multiply it by the scale factor to have the normalized control signal. We present in figure 4 below the implementation of our fuzzy regulator.

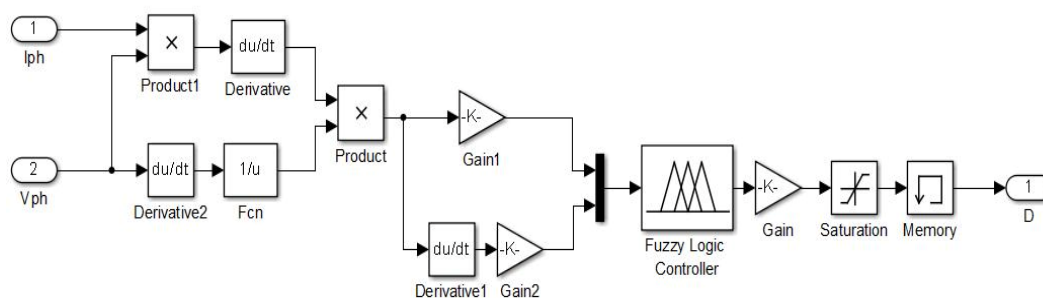

Figure 4: Simulink model of the fuzzy regulator

### 2.2.2.3: DC-AC Converter: Single-Phase Inverter

The single-phase inverter illustrated by its Simulink model (Figure 5) allows the manufacture of alternating voltage

from the DC voltage on the chopper. The pulse width modulation (PWM) technique is used to control the switching bridge of the inverter.

Figure 5: Simulink Model of the Single-Phase Inverter

The pulses ( $G_1, G_2, G_3$  and  $G_4$ ) of the switches (IGBT) of the same arm are complementary and generated by the MLI

control implemented in the following Figure 6.

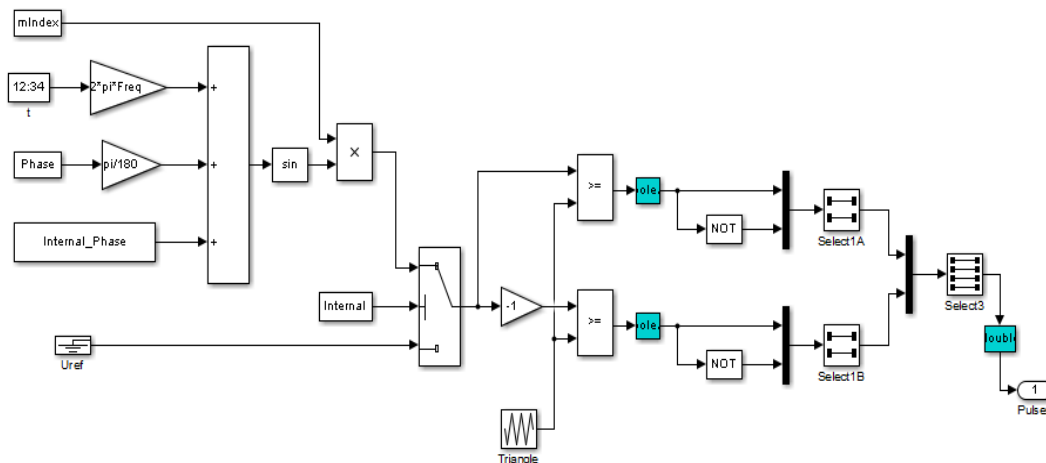

Figure 6: PWM Implementation

**2.2.3 Implementing Adaptive Control by Reference Model**

The submersible pump is the most important module of the photovoltaic pumping system. Several parameters and factors prevent its optimal operation. These parameters are meteorological, electrical, mechanical and hydraulic. Adaptive control of the rotational speed of the pump motor

is the best method to optimise its operation. We have developed a method to regulate the speed of rotation of the pump motor regardless of the parameters and factors that influence it. We present in figure 7 below, the "Simulink" model of the fuzzy control loop of the rotational speed of the submerged pump motor.

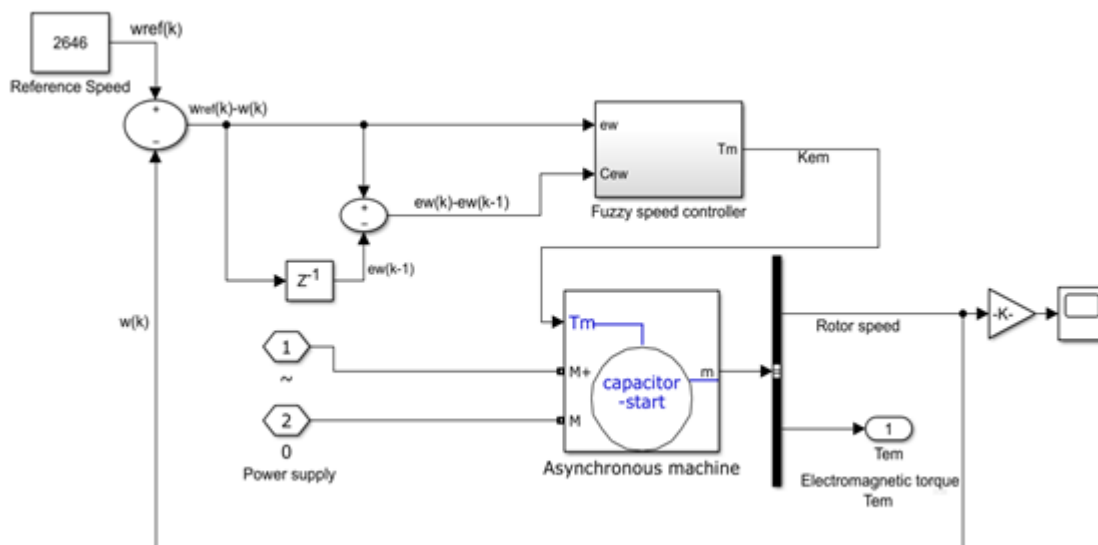

Figure 7: "Simulink" model of the fuzzy pump speed control.

As shown in Figure 7, the entries of the fuzzy regulator are calculated at time  $k$  from the following equations 8 and 9.

$$e_w(k) = w_{ref}(k) - w(k) \tag{8}$$

$$Ce_w(k) = e_w(k) - e_w(k-1) \tag{9}$$

The control signal provided by the fuzzy regulator corresponds to the mechanical torque  $T_m(k)$  of the pump motor, obtained by the centre of gravity method as shown in relation 10.

$$T_m(k) = \frac{\sum_{k=1}^n \mu(T_m(k)) \cdot T_m(k)}{\sum_{k=1}^n \mu(T_m(k))} \tag{10}$$

After several simulation tests we established the following ranges of input and output quantities:

- Speed error  $e_w(k) : [-400 ; 400]$  rad/s ;
- Speed error change  $Ce_w(k) : [-2 ; 2]$  rad/s ;
- Mechanical torque change  $T_m(k) : [-0,5 ; 0,5]$  N.m .

To distribute this data in the blurred spaces, we first defined the fuzzy sets. In general, we introduce for a variable  $x$ , three, five or seven sets. A finer subdivision, i.e. more than seven sets, generally does not improve the dynamic behaviour of the control by fuzzy logic. On the other hand, such a choice would complicate the formulation of the regulator setting by fuzzy logic. After several experiments and simulations, we find that, to increase the robustness of the fuzzy regulator towards the engine parameters, it is advantageous to choose a greater density around the zero

value of a quantity. Figure 8 shows the fuzzy distribution diagram for the input quantities of the cruise control used in this part. The triangular shape is used for membership functions except for the ends of each membership function where the trapezoidal shape is used. The fuzzy distribution is symmetrical, not equidistant. The meaning of the symbols and the ranges of value designated to the fuzzy sets are shown in Table 2.

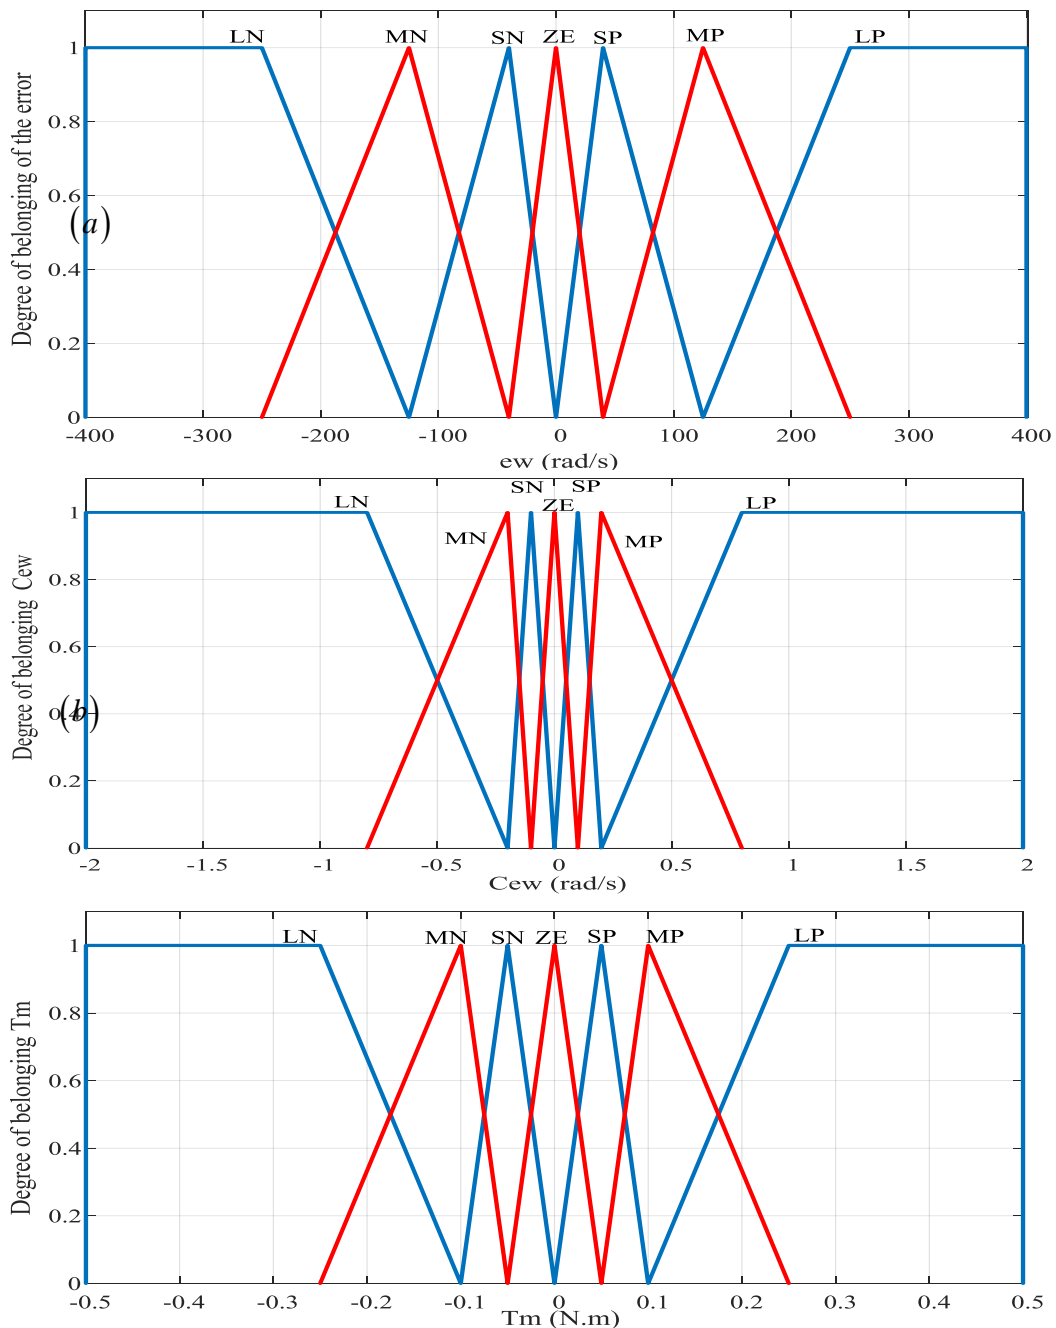

Figure 8: Membership functions of: (a) the  $e_w$  entry; (b) the  $C_{e_w}$  input and (c) the  $T_m$  output of the fuzzy cruise control.

Table 2: Fuzzification of the assemblies for cruise control

Meaning	Symbol	Speed error $e_w$ (rad/s)	Speed error change $C_{e_w}$ (rad/s)	Mechanical torque change $T_m$ (N.m)
Large negative	LN	-400 $\rightarrow$ - 125	-2 $\rightarrow$ - 0, 2	-0, 5 $\rightarrow$ - 0, 1
Medium negative	MN	-125 $\rightarrow$ - 40	-0, 8 $\rightarrow$ - 0, 1	-0, 25 $\rightarrow$ - 0, 05
Small negative	SN	-125 $\rightarrow$ 0	-0, 2 $\rightarrow$ 0	-0, 1 $\rightarrow$ 0
About zero	ZE	-40 $\rightarrow$ 40	-0, 1 $\rightarrow$ 0, 1	-0, 05 $\rightarrow$ 0, 05
Small positive	SP	0 $\rightarrow$ - 125	0 $\rightarrow$ 0, 2	0 $\rightarrow$ 0, 1

Medium positive	MP	40 → 250	0, 1 → 0, 8	0, 05 → 0, 25
Large positive	LP	125 → 400	0, 2 → 2	0, 1 → -0, 5

### 2.2.4 Simulink Model of the Submerged Electric Pump

We show in Figure 8 below the Simulink model of the single-phase motor coupled to the centrifugal pump.

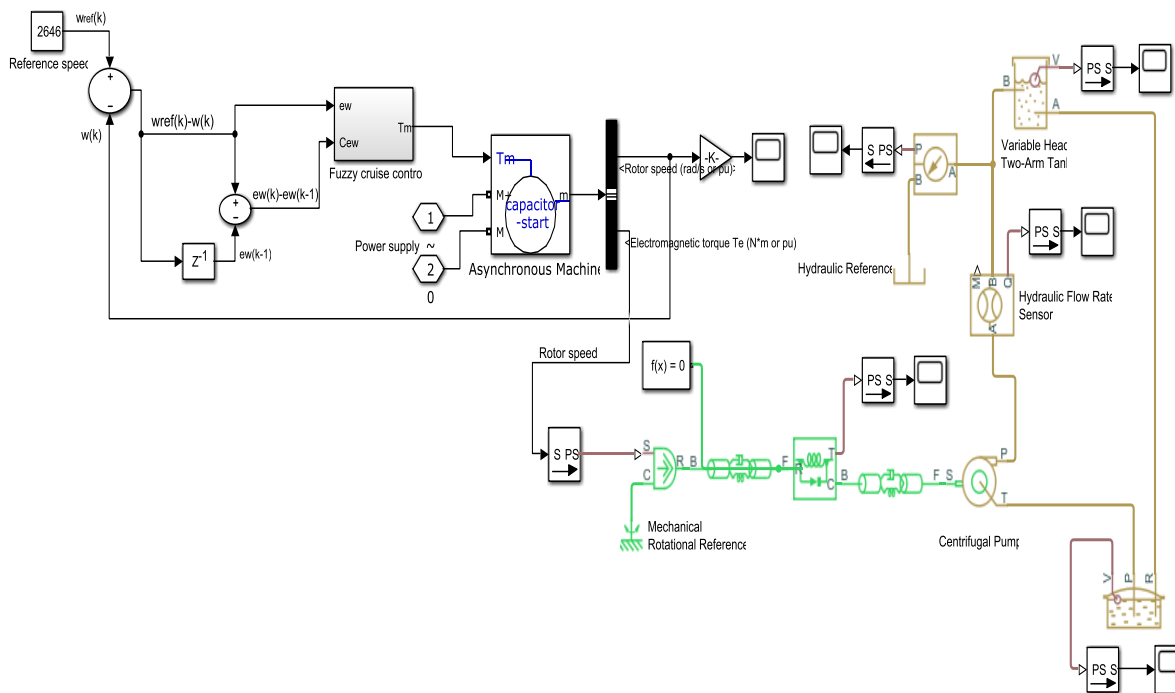

Figure 8: Simulink model of the single-phase motor coupled to the centrifugal pump

## 3. Results and discussion

### 3.1 Influences of irradiance and temperature variation on GPV

Figure 11 shows the behaviour of irradiance and temperature during a day (from 9 am to 4 pm) at the University of

Figure 11: Irradiance and temperature curves during a day.

### 3.2 Impact of the MPPT-Fuzzy controller on the voltage from the GPV

Having the certainty that the GPV is working normally, it is thus possible to power the complete system. The fluctuation of the voltage at the terminals of the GPV between 38.21 V and 55.4 V as shown in Figure 14 allows us to conclude at

Ngaoundere Cameroon. We find that the irradiance reaches its maximum value at about 12 hours and then begins to fall. These curves allow us to conclude that meteorological parameters in Adamawa fluctuate constantly.

first that powering an electric pump over the sun and expecting a regular flow of water is almost impossible. But thanks to the MPPT-blur control performed at the chopper input, the voltage was boosted and made almost stable at the average value of 222.3 V (Figure 15). Figure 15 through these two curves makes a comparison of the voltages at the output of the booster chopper under the "MPPT-P&O"

command and under the "MPPT-blur" command. The analysis of these curves shows that the "MPPT-blur" control optimises and stabilises the voltage from the GPV better than the "MPPT-P&O specific" command.

Figure 14: Voltage at GPV output.

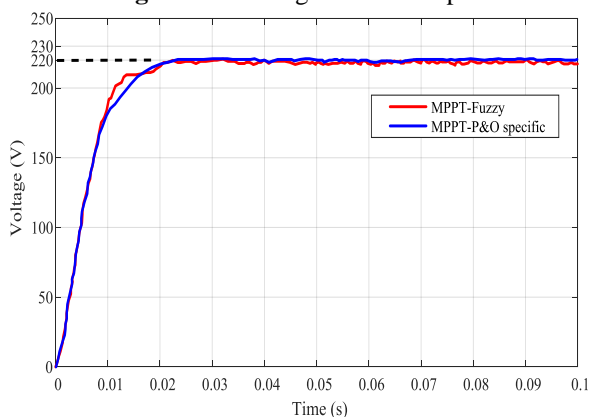

Figure 15: Tension at the outlet of the chopper.

The DC voltage from the chopper is applied to the input of the inverter, we obtain at the output an alternating voltage of amplitude 223.7 V with a modulation index of 0.98 and a period of 0.02 s (Figure 16). In order to obtain a frequency of 50 Hz according to the nominal frequency of the electric pump, a low pass filter is placed at the output of the inverter as modelled in Figure 5.

Figure 17 shows the speed of rotation of the motor driving the centrifugal pump. We notice that when the weather conditions are favourable, the engine quickly reaches its permanent speed (2820 rpm). This result is consistent with that found in [10] and [11] with the only difference that the P&O controller replaced by Mandani's fuzzy controller improves the response time of the motor.

Figure 16: Voltage at the outlet of the inverter

Figure 17: Motor rotation speed

At the same time, we studied the influence of the viscosity of the pumped fluid on the speed and electromagnetic torque of the electropump. From the analysis of the curves in Figures 17 and 18, we see that the rotational speed and torque of the motor decreases when the viscosity of the fluid to be pumped becomes greater and greater. Thus, a highly viscous fluid can prevent the pump from turning thus reducing its efficiency to zero.

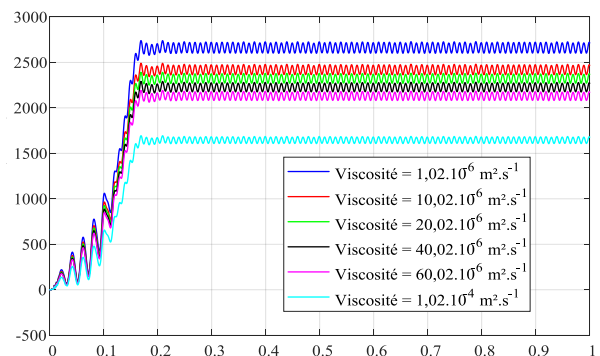

Figure 17: Influence of viscosity on velocity

Figure 18: Influence of viscosity on engine torque

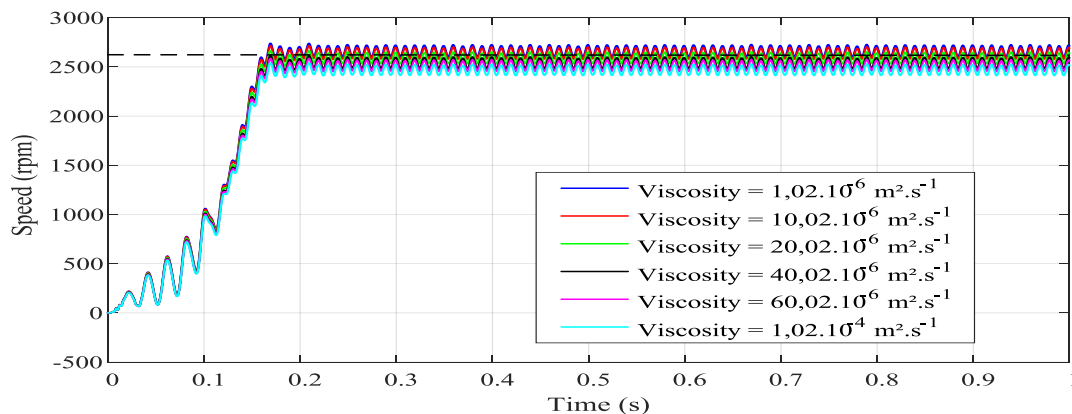

Figure 19: Behaviour of the rotational speed after adaptation regulation

By varying the viscosity of the pumped fluid, we find that the rotational speed of the submerged pump motor does not deviate much from the average reference speed (2646 rpm) that must be followed by the fuzzy cruise control. We present in Table 3, the rotational speeds of the submerged electropump before and after regulation, for different viscosity values.

Table 3: Speeds before and after regulation as a function of the viscosity of the pumped fluid.

Fluid viscosity (m <sup>2</sup> .s <sup>-1</sup> )	Speed before regulation (rpm)	Speed after regulation (rpm)
1, 02.10 <sup>-6</sup>	2646	2646
10, 02.10 <sup>-6</sup>	2463	2629
20, 02.10 <sup>-6</sup>	2237	2567
40, 02.10 <sup>-6</sup>	2221	2544
60, 02.10 <sup>-6</sup>	2076	2532
1, 02.10 <sup>-4</sup>	1734	2502

When the submerged electric pump operates without a control loop for different values of the viscosity of the pumped fluid, the average speed of the electropump is 2230 rpm, a difference of 416 rpm from the reference speed. By using the fuzzy regulator, the electropump keeps an average speed of 2570 rpm or a difference of 76 rpm. We therefore come to the conclusion that the use of adaptive blur control by reference model makes it possible to optimize by 340 rpm the average speed of rotation of the submerged electropump regardless of the viscosity of the pumped fluid.

#### 4. Conclusion

In this work, it was a question of proposing a strategy for optimizing the operation of photovoltaic pumping systems in

### 3.3 Impact of Fuzzy Adaptive Control by Reference Model on Electropump Speed

Figure 19 shows the different behaviours of the rotational speed of the electropump under several values of the viscosity of the pumped fluid using the fuzzy adaptive control by reference model.

the face of variations in meteorological parameters and the viscosity of the pumped fluid. The use of the fuzzy MPPT algorithm for the control of the chopper control pulses, allows the optimal conversion of irradiance. Adaptive reference model control with a status observer, forces the controlled electric pump to follow the desired reference speed, using a control law based on fuzzy logic, for real-time automatic adjustment of the pump's rotational speed. The simulation results obtained are appreciable in terms of robustness, with regard to the presence of disturbances.
