Abstract

The Zagreb indices plays vital role in chemical graph theory. In this paper we put forward a new variations of Zagreb indices, we call it as the mean Zagreb Indices. Further, we show that these parameters are highly correlated with physical properties of octane isomers. Finally we carry out QSPR (Quantitative Structure-Property Relationship) analysis using several physicochemical properties of octane isomers.

1 Introduction

Let $G = (V, E)$ be a graph. The number of vertices of $G$ we denote by $n$ and the number of edges we denote by $m$, thus $|V(G)| = n$ and $|E(G)| = m$. For undefined terminologies we refer the reader to [8].

A graph invariant is any function on a graph that does not depend on a labeling of its vertices. Such quantities are also called topological indices. Hundreds of different invariants have been employed to date (with unequal success) in QSAR/QSPR studies. Among more useful of them appear two that are known under various names, but mostly as Zagreb indices. Due to their chemical relevance they have been subject of numerous papers in chemical literature. There are two invariants called the first Zagreb index and second Zagreb index [1, 2, 5–7, 9–12, 14], defined as

$$M_1(G) = \sum_{u \in V(G)} d_G(u)^2$$

and

$$M_2(G) = \sum_{uv \in E(G)} d_G(u) d_G(v),$$

respectively.
In fact, one can rewrite the first Zagreb index as

\[ M_1(G) = \sum_{uv \in E(G)} [d_G(u) + d_G(v)]. \]

Noticing that contribution of nonadjacent vertex pairs should be taken into account when computing the weighted Winer polynomials of certain composite graphs (see [1] defined first Zagreb coindex and second Zagreb coindex as

\[ \overline{M}_1(G) = \sum_{uv \notin E(G)} [d_G(u) + d_G(v)] \quad \text{and} \quad \overline{M}_2(G) = \sum_{uv \notin E(G)} d_G(u) d_G(v), \]

respectively.

The Forgotten Topological Index [4] is defined as

\[ F(G) = \sum_{u \in V(G)} d_G(u)^3. \]  \( (1) \)

Miličević et. al [13] reformulated the Zagreb indices in terms of edge-degrees instead of vertex-degrees:

\[ EM_1(G) = \sum_{e \in E(G)} d_G(e)^2 \quad \text{and} \quad EM_2(G) = \sum_{e \sim f \in E(G)} d_G(e) d_G(f), \]

where \( d_G(e) \) denotes the degree of an edge \( e = uv \) in \( G \), which is defined by \( d_G(e) = d_G(u) + d_G(v) - 2 \) and \( e \sim f \) means that the edges \( e \) and \( f \) are adjacent.

Noticing that contribution of nonadjacent edges pairs should be taken into account, the reformulated Zagreb coindices can be defined as:

\[ EM_1(G) = \sum_{e \notin f \in E(G)} [d_G(e) + d_G(f)] \quad \text{and} \quad EM_2(G) = \sum_{e \sim f \notin E(G)} d_G(e) d_G(f), \]

where \( d_G(e) \) denotes the degree of an edge \( e = uv \) in \( J(G) \), which is defined by \( d_{J(G)}(e) = m + 1 - (d_G(u) + d_G(v)) \) and \( e \sim f \) means that the edges \( e \) and \( f \) are non adjacent.

We define a new degree invariant and call it as the mean degree of a vertex \( v \in V(G) \). Which is defined as \( \text{deg}_a(v) = \frac{\sum_{u \sim v} \text{deg}(u)}{\text{deg}(v)}. \)

Motivated by the earlier research on topological indices, here we conceive a new degree based topological index in terms of mean degree of a vertex, we call it as the first mean Zagreb index and is is defined as follows:

\[ M_1^a(G) = \sum_{u \in V(G)} \text{deg}_a(u)^2. \]  \( (2) \)
To illustrate our concept, consider the graph $G$ which is depicted in Fig.1.

![Graph G](image)

Figure 1.

The mean degrees of each vertex in $G$ is given by

$$
deg_a(u) = \frac{3+1}{2} = 3; \quad deg_a(v) = \frac{1+2+2}{3} = \frac{5}{3},$$

$$
deg_a(w) = deg_a(x) = \frac{3+2}{2} = \frac{5}{2}.$$  

Therefore, the the first mean Zagreb index is $M_1^a(G) = 18.0277$.

## 2 QSPR Analysis of the First Average Zagreb Index

Here we have examined the chemical applicability of the first mean Zagreb index and compared the values with the so called degree based topological indices, namely, first Zagreb index $M_1(G)$, second Zagreb index $M_2(G)$, first Zagreb coindex $\overline{M}_1(G)$, second Zagreb coindex $\overline{M}_2(G)$, Forgotten index $F(G)$, first reformulated Zagreb index $EM_1(G)$, second reformulated Zagreb index $EM_2(G)$, first reformulated Zagreb coindex $\overline{EM}_1(G)$, second reformulated Zagreb coindex $\overline{EM}_2(G)$ for modeling ten representative physical properties [boiling points (BP), molar volumes (mv) at 20°C, molar refractions (mr) at 20°C, heats of vaporization (hv) at 25°C, surface tensions (st) 20°C and melting points (mp), acentric factor (AcentFac) and DHVAP] of octane isomers. The $M_1^a(G)$ was tested using a data set of octane isomers found at http://www.moleculardiscriptors.eu/dataset.htm.

## 3 Data based and analytical method

Eight physicochemical properties of octane isomers have been selected on the availability [15] of a suitable body of data: boiling point (BP), critical temperature (CT), critical
pressure (CP), entropy (S), density (D), mean radius ($R_m^2$) and heat of vaporization ($H_v$), heat of formation ($H_f$). The values are compiled in Table 1.

4 Results and Discussion

From table 2, it is found that the correlation coefficient of the degree based topological indices with physicochemical properties of isomers are found to be good except critical
pressure heats of vaporization and heats of formation.

A generalized linear regression model has been proposed for the relationship of physicochemical properties of octane isomers with the $M_1^a(G)$, $M_1(G)$, $M_2(G)$, $M_1(G)$, $M_2(G)$, $F(G)$, $EM_1(G)$, $EM_2(G)$, $EM_1(G)$ and $EM_2(G)$ respectively.

$$P = a + \sum_{i=1}^{10} b_i X_i$$  \hspace{1cm} (3)

where $P$ refers to a physicochemical property, $a$ is constant, $b_i$ the sensitivity of $X_i$ towards $P$. For our convenience we assume $X_1 = M_1^a(G)$, $X_2 = M_1(G)$, $X_3 = M_2(G)$, $X_4 = M_1(G)$, $X_5 = M_2(G)$, $X_6 = F(G)$, $X_7 = EM_1(G)$, $X_8 = EM_2(G)$, $X_9 = EM_1(G)$ and $X_{10} = EM_2(G)$

We first consider the regression model containing single descriptors $M_1^a(G)$, $M_1(G)$, $M_2(G)$, $M_1(G)$, $M_2(G)$, $F(G)$, $EM_1(G)$, $EM_2(G)$, $EM_1(G)$ and $EM_2(G)$ respectively.

$$P = a + bM_1^a(G)$$  \hspace{1cm} (4)

$$P = a + bM_1(G)$$  \hspace{1cm} (5)

$$P = a + bM_2(G)$$  \hspace{1cm} (6)

$$P = a + bM_1(G)$$  \hspace{1cm} (7)

$$P = a + bM_2(G)$$  \hspace{1cm} (8)

$$P = a + bF(G)$$  \hspace{1cm} (9)

$$P = a + bEM_1(G)$$  \hspace{1cm} (10)

$$P = a + bEM_2(G)$$  \hspace{1cm} (11)

$$P = a + bEM_1(G)$$  \hspace{1cm} (12)

$$P = a + bEM_2(G)$$  \hspace{1cm} (13)
The correlation coefficients of physicochemical properties with individual $M_1^a$ values show some significant results. The first mean Zagreb index is found to be useful to predict the DHVAP of octane isomers with correlation coefficient value 0.849 which is prediction power is better than second Zagreb index (0.801), second Zagreb coindex (0.819), reformulated Zagreb index (0.820), first reformulated Zagreb coindex (0.306) and second reformulated Zagreb coindex (0.780) respectively. Further, the predicting power of $M_1^a$ in sensing acentric factor of octane isomers with correlation coefficient value 0.831 is far better than the predicting power of other topological indices, such as first reformulated Zagreb coindex (0.063) and second reformulated Zagreb coindex (0.579) respectively. The one more application of $M_1^a$ is to QSPR studies is found to be the prediction of entropy value of octane isomers with correlation coefficient value 0.810 which is far better than the first reformulated Zagreb coindex (0.138) and second reformulated Zagreb coindex (0.580) respectively.

The regression analysis of models (4)-(13) with single descriptors, reveals some interesting results for physicochemical properties of octane isomers. The range of $R$, $S$ and $F$ for each physical property of octane isomers are as follows:

For boiling point the range of $R$, $S$ and $F$ are 0.518 – 0.727, 0.351–4.574 and 7.131–20.996 respectively. Next, for critical temperature of octane isomers the range of $R$, $S$ and $F$ are 0.164 – 0.730, 6.8665 – 9.9589 and 0.262 –18.203 respectively, for critical pressure, density, heats of vaporization and heats formation all these parameters shows bad results. Finally for entropy and acentric factor of octane isomers above models (4-13) are most suitable models. As an example, we show the correlation coefficient of the above mentioned topological indices with the DHVAP of octane isomers in the following graphs:
Conclusion. The results of QSPR studies reveals that the regression model (3) is the most significant model to predict the physicochemical properties of molecular graphs. Hence the first mean Zagreb index is an important tool in the area of QSPR studies. Analogous to the second Zagreb index and forgotten index, we have defined the Second mean Zagreb index and forgotten mean index and results on the topics are under process.
