**Abstract:** *Today computer science has reformed our world and machines have gotten to be basic part of our life. It made it simple for us to investigate and diagnose the medical issues and diseases. The utilization of Artificial Intelligence in drug and medical sciences are on appeal. This paper concentrates on the attributes of Clinical Decision Support System and the systems utilized for their execution. It talks about how they are useful in judgment of illnesses. The reason for this careful investigation is to study the parts of Clinical Decision Support Systems and to evaluate the most ideal strategy that can be utilized within Clinical Decision Support Systems to give the best arrangements and conclusion to restorative problems. The purpose of a precise system relies on different parameters of available domain. Such systems are powerful in one of the space while other may be significantly more compelling in different areas. Privacy preserving is an important task to preserve important data for clinical decision support system where the patient data kept in encrypted form during diagnosis process.*

**Keywords:** Privacy preserving, Artificial Intelligence, clinical, Decision Support System.

## 1. Introduction

Computer science is presently getting much more included in the drug science, health sciences. The area of computer science which is all the more energetically and effectively included in medicinal sciences is Artificial Intelligence. With support of Artificial Intelligence Different Clinical Decision Support Systems have been built. These frameworks are presently broadly utilized within healing facilities and clinic. They are turned out to be exceptionally valuable for patient and for medicinal specialists in making decisions. Different philosophies are put to use for the enhancement of those frameworks. The best available method for gathering the data and to present output data is distinctive in diverse strategies. Any machine program that helps specialists in settling on clinical choice goes under the space of clinical decision support system. An vital property for the AI is that it can help the development and best use of the clinical information. Utilizing Artificial Intelligence we can make the frameworks that will have the ability to learn and the formation of new clinical information [2].

This issue of securing critical private data of associations/organizations is referred as corporate security [1]. Like personal defense, which just considers the agreement of the data, recorded about people, for security purpose it is requires that both the individual things and the examples of the accumulation of information things. Protection Preserving Data Mining (PPDM) is a research area concerned with the protection determined by identifiable data when considered for data mining. Hence, PPDM has turned into an increasingly paramount field of research. PPDM is a novel approach research in data mining. Various methods and procedures have been produced for protection protecting Preserving privacy is a research zone concerned with the security determined from generally identifiable data at the point when considered. This work

focuses the security issue by considering the protection and algorithmic prerequisites at the same time.

So in particular use of privacy preserving is important task to protect patient data from external or third party servers which are generally untrusted server. Decision support system is generally made up of SVM (Support Vector Machine). It is use widely for one of the application as biomedical tool for predicting disease [3][4][5]. In this paper we surveyed on various clinical decision support system as well as privacy protection in Section II as literature review. In Section III we conclude by presenting various approaches at last.

## 2. Literature Review

The main objective of this is to present recent trends in Clinical decision support system. We will discuss different methodologies used regarding Health care.

### a. History in Clinical Decision Support System

Since machine was invented, it has been utilized for aiding medicinal experts. The first research article which manages prescription also machines showed up in late 1950s (Ledley & Lusted, 1959). Later an experimental model showed up in the early 60s (Warner et al., 1964). Around then restricted abilities of machine did not permit it to be a part of medical space. In 1970s the three report frameworks: de Dombal's framework for determination of stomach pain (de Dombal et al., 1972), Shortliffe's MYCIN framework for anti-infection agents choice (Shortliffe, 1976), and HELP framework for medical alert delivery (Kuperman et al., 1991; Warner, 1979). 1990s saw a vast scale shift from administrative frameworks to clinical decision support systems.

### b. Decision Support System using Artificial Intelligence

Clinical Decision support system (CDSS) is broadly classified into two types:

1. Knowledge base
2. Non-Knowledge base

### Knowledge Base CDSS

The information based clinical decision supportive system contains rules basically as IF-Then statements. The information is generally attached with these rules. In case if the hurting is at the definite level then create alarm and so forth., The knowledge based for the most part comprises of three principle parts. Knowledge base, Inference rules and an communication mechanism. Knowledge base contains the guidelines, inference engine joins principles with the patient information and the correspondence system is utilized to demonstrate the result to the clients and in addition to give data to the framework. In certain case, for example, of chest pain management, the knowledge base rules from a learning base server end up being substantially more powerful than others [6]. They are the commonest kind of Clinical Decision Support System utilized as a part of hospitals and clinics. They can have clinical knowledge around an uncommonly characterized assignment, or can even have the capacity to work with case base reasoning. The information in specialist system is presented as set of rules. Frequently the knowledge based is utilized with change management to execute patient forethought prepare and give amazing social insurance benefits like health care progressively. This knowledge based management framework is actualized utilizing the object oriented analysis, UML strategies and treatment of difference through the development of fuzzy ECA (GFECA) rules [7].

### Non Knowledge Based CDSS

CDSS without a learning base are called as non-knowledge based CDSS. These frameworks rather utilized a type of artificial intelligence called as machine learning. There are two main classes of Non- knowledge based CDSS.

First is Neural Network. To infer relationship between the systems and diagnosis, neural systems utilize the nodes and weighted connections. It concludes that there is no need to compose various rules for input. Besides that, the framework disregards to illuminate the explanation, utilizing of the information. So its dependability and accountability can be a reason. It has been noticed that the self-arranging tactic of preparing the neural system in which it isn't given any convent data about the classifications it is obliged to recognize, is fit for concentrating applicable data from info information so as to create clusters compare to class. in addition it requires little scope of accessible information to set up the system [8].

Second type is the genetic algorithm which is focused around evolutionary methodology. Selection algorithm assesses segments of answers for an issue. Solution that goes ahead on top are recombined and the procedure runs again until a legitimate solution is observed. The generic framework denotes an iterative model to deliver the reason the best solution of an issue. It likewise clarifies that there is a chance to actualize clinical decision supportive system utilizing genetic algorithm. This is the point of future

### c. Defining Privacy Preserving

All in all, privacy preservation happens in two major measurements: user's personal data and data concerning their aggregate action. We can see the previous as personage protection conservation and the recent as group privacy conservation, which is identified with corporate privacy). in (Clifton et al., 2002

**Individual protection conservation:** The essential objective of information protection is the assurance of by and by identifiable data. All in all, data is considered generally identifiable on the off chance that it can be joined, straightforwardly or by implication, to a unique individual. Hence, when individual information is subjected to mining, the trait values connected with people are private and must be secured from disclosure. Miners are then ready to learn from worldwide models instead of from the attributes of a specific single person.

**Collective security conservation:** Protecting individual information may not be sufficient. Once in a while, we may need to make sure beside learning insightful information speaking to the activities of a group. Defence of sensitive learning can be refer as collective privacy preservation. The objective here is very like that one for statistical databases, in which security control mechanism give total data about group of people and, in the meantime, anticipate disclosure of classified data about people. It may, different to as is the situation for statistical databases, an alternate goal of aggregate security protection is to secure sensitive data that can give advantage in the business world [9].

### 3. Conclusion

There are diverse approaches for executing the clinical Decision support system. It is observed that a few systems are domain based. They are effective for only the particular sicknesses domain. Though, some are generally helpful in all the areas. The determination of a specific procedure additionally relies on some outside parameters, for example, the expense of framework; require effectiveness, and measure of information accessible and the affectability of the framework. In future, the learning from this paper can be reused as a thesis work or as a research itself. For the purpose of protecting patient's data encryption based technique is useful. Patient's data is encrypted all the time even during the diagnosis process.
