Maximum Power Generation by Integrating Solar & Wind System Using Fuzzy for Voltage Regulation in Smart Grid

Priya .N¹, Saranya .C .M²

Department of Power System Engineering, Valliammai Engineering College, Chennai, India

Abstract: This paper presents the voltage regulation of hybrid power system with the inter connection of PV system, wind energy conversion system. The voltage regulation is done with the help of fuzzy logic controller and zeta converter through simulations using MATLAB / SIMULINK. In the proposed system the solar energy and wind energy is combined to produce electrical energy. Then power electronic converters are used for the conversion of ac to dc and dc to ac. In which a control circuit is designed using fuzzy logic controller for gate signals for the voltage regulation of the hybrid energy system. Then the hybrid energy system is connected to the grid from which the energy is supplied to the loads. The voltage regulation is done for both AC and DC loads.

Keywords: Hybrid power systems, Photovoltaic systems, Smart grids, Wind power generation, Fuzzy Logic Controller

1. Introduction

According to many renewable energy experts, a small "hybrid" electric system that combines home wind electric and home solar electric (photovoltaic or PV) technologies offers several advantages over either single system[1]. In some countries wind speeds are low in the summer when the sun shines brightest and longest. The wind is strong in the winter when less sunlight is available. Because the peak operating times for wind and solar systems occur at different times of the day and year, hybrid systems are more likely to produce power when you need it. The major advantage of solar / wind hybrid system is that when solar and wind power production are used together, the reliability of the system is enhanced[3].The ZETA converter topology provides a positive regulated output voltage from an input voltage that varies above and below the output voltage. It is also used to regulating an unregulated input-power supply.

Fuzzy logic has rapidly become one of the most successful of today's technology for developing sophisticated control system. With it aid complex requirement so may be implemented in amazingly simple, easily minted and inexpensive controllers. The past few years have witnessed a rapid growth in number and variety of application of fuzzy logic[9]. The application range from consumer products such as cameras ,camcorder ,washing machines and microwave ovens to industrial process control ,medical instrumentation ,and decision support system .many decision-making and problem solving tasks are too complex to be understand quantitatively however .people succeed by using knowledge that is imprecise rather than precise . Fuzzy logic is all about the relative importance of precision .fuzzy logic has two different meanings .in narrow senses, fuzzy logic is a logical system which is an extension of multi valued logic but in wider sense fuzzy logic is synonymous with the theory of fuzzy sets.

2. System Description and Modeling

In hybrid power systems, a number of renewable energy generators and storage components are combined to meet the energy demand of the power system. It mainly includes PV generators and wind generators, the others sources of electrical energy can also be added to meet the energy demand. It is essential to know the energy demand and the resources available at that site before developing a hybrid power system. The energy planners must study the availability of solar energy, wind, and other potential resources at that site. This will help them to design what kind of hybrid power system will be suitable to meet the demand. In this paper, a brief technical description of some of the different hybrid power system configurations is considered in Fig1.

A. Modelling and Design of a Photovoltaic Module

The circuit of the solar cell model, which consists of a photocurrent, diode, parallel resistor (leakage current) and a series resistor; is shown in Fig. 3. According to both the PV
cell circuit shown in Fig. 3 and Kirchhoff’s circuit laws, the photovoltaic current can be presented as follows,

\[ I_{PV} = [I_{GC} - I_0 \exp\left(\frac{eVd}{kTc}\right) - 1] - \frac{Vd}{R_P} \]

Figure 2: Single Diode Model of a PV Cell

electric charge = 1.6 x 10^{-19} Coulombs,
\( K \) is Boltzmann’s constant = 1.38 x 10^{-19} J/K,
\( F \) is the cell idealizing factor,
\( T_c \) is the cell’s absolute temperature,
\( V_d \) is the diode voltage,
and \( R_P \) is the parallel resistance.

The photocurrent \( (I_{GC}) \) mainly depends on the solar irradiation and cell temperature,

The output current from the photovoltaic array is

\[ I = I_{SC} - I_d \]

\[ I_d = I_0 \left( e^{Vd/kT} - 1 \right) \]

\[ I = I_{SC} - I_0 \left( e^{VqIR/kT} - 1 \right) \]

Where, \( I \) is the photovoltaic cell current,
\( V \) is the PV cell voltage,
\( T \) is the temperature (in Kelvin)

B. Wind Power Generation System

According to both the PV cell circuit shown in Fig. 3 and Kirchhoff’s circuit laws, the photovoltaic current can be presented as follows

\[ I_{PV} = \left[ I_{GC} - I_0 \exp\left(\frac{eVd}{kTc}\right) - 1 \right] - \frac{Vd}{R_P} \]

Wind turbine model

A wind turbine converts kinetic energy in a moving air stream to electric energy. The wind turbine model is implemented depending upon the Tip Speed Ratio (TSR) and \( C_p \) coefficient. The tip-speed ratio is defined as:

\[ \lambda = \frac{\omega R}{V} \]

- Power in wind is proportional cube of wind speed
\[ P = 0.5 \rho A V^3 C_p \]

Where,
\( \rho \) = Air density
\( A \) = Area swept by blade
\( V \) = Wind speed

- A wind turbine can only extract a part of the power from the wind, which is limited by Beta.
- This fraction is described by the power coefficient \( C_p \) which is the function of blade pitch angle (\( \beta \)) and tip speed ratio (\( \lambda \)).

C. Power Control System

1. Photovoltaic control system

MPPT algorithms are necessary in PV applications in order to obtain the maximum power from a solar array because the MPP (Maximum Power Point) of a solar panel varies with the irradiation and temperature. The incremental conductance uses the PV array's incremental conductance \( dI/dV \) to compute the sign of \( dP/dV \).

It does this using an expression derived from the condition that, at the maximum power point, \( dP/dV = 0 \). Beginning with this condition, it is possible to show that, at the MPP \( dI/dV = V/I \). Thus, incremental conductance can determine that the MPPT has reached the MPP and stop perturbing the operating point.
If this condition is not met, the direction in which the MPPT operating point must be perturbed can be calculated using the relationship between $dI/dV$ and $I/V$. The algorithm is simulated by writing the algorithm in M-file. The subsystem is shown in below figure

![Figure 5: Subsystem Implementation of incremental conductance algorithm](image)

**D. Double Bridge Rectifier and ZETA Converter**

Due to the variations in wind speed, the output power of the wind turbine induction generator experiences variations in frequency and amplitude. Therefore, a controllable ac/dc converter is used to smooth the wind turbine output power before being supplied to other electronic devices.

The ZETA converter topology provides a positive regulated output voltage from an input voltage that varies above and below the output voltage. It is also used to regulating an unregulated input-power supply. Zeta converter is a fourth-order DC-DC converter made up of two inductors and two capacitors and capable of operating in either step-up or step-down mode.

**E. Fuzzy Logic Controller**

Fuzzy logic expressed operational laws in linguistics terms instead of mathematical equations. Many systems are too complex to model accurately, even with complex mathematical equations; therefore traditional methods become infeasible in these systems. The fuzzy logic controller has three main components

- a. Fuzzification
- b. Fuzzy inference
- c. Defuzzification

Fuzzy logic linguistic terms are often expressed in the form of logical implication, such as if then rules. These rules define a range of values known as fuzzy membership functions. The inputs of the fuzzy controller are expressed in several linguistic levels. As shown in the table,

<table>
<thead>
<tr>
<th>Change in error (e)</th>
<th>Error (e)</th>

3. Simulation and Analysis of Results

In this overall simulations shows the integration of solar and wind energy system, constant 0.5 refers input current to the PV panel and 85 is the insolation of the PV panel which can be varied due to the change in climatic condition. PV Module requires the input current and insolation. The Output of the PV panel given to the controlled voltage source.

Based on the simulation result voltage range from 0-114V and the current value nearly 115A obtained from the solar panel. Hence this is given as an input of Boost converter and also to MPPT.

Boost converter (step-up converter) is a DC-DC power converter with an output voltage greater than its input voltage. Boost type dc-dc converter is used to feed the power generated by the PV array to the load. The input of Boost converter is about 114V but the gained output voltage ranges from 550-600V is simulated using MATLAB.

Zeta converter is used to regulating an unregulated input-power supply. Regulated output voltage obtain from the zeta converter ranges from 450-500V to feed the load.
4. Conclusion

The results show that obtaining Maximum Power by using MPPT-Incremental conductance method. And also by DC-DC Boost converter, the voltage level is gained to feed the load. DC-DC converters (Boost) are analyzed with a view of their use in PV (photovoltaic) systems, as the photovoltaic generator exhibits non-linear characteristics due to the change in environmental condition and load variation. As the efficiency of PV panels is low it becomes mandatory to extract maximum power from the PV panel at a given period of time, hence the load voltage is maintained constant. Regulated voltage is obtained by using zeta converter under fuzzy logic controller.
