2.4 Soil chemical factors analysis

Soil samples are air dried and sieved, from this soil samples the chemical factors like nitrogen, phosphorus, potassium, calcium, and magnesium were analyzed. The nitrogen content was analyzed by Kjeldahl distillation method, the phosphorous content was analyzed by Molybdate stannous chloride method, potassium content was analyzed by flame photometry method (APHA, 2012). The calcium and magnesium content of the soil were analyzed by the methods of Jackson (1958).

2.5 Statistical analysis

Descriptive statistics were done by using Microsoft excel software. Two way Analysis of variance (ANOVA) was conducted to determine any significant difference in the value of each parameter between sites and seasons using SPSS package 14.00.

3. Result

3.1 Agricultural habitat

3.1.1Soil edaphic factors

In agricultural habitat the soil edaphic factors like soil temperature, pH, exchangeable acid, exchangeable base, organic carbon content, moisture content, sand, silt, and clay content were detected.

Soil temperature in agricultural land was at an average of 27.3 ^{0}C in pre monsoon, 24.2 ^{0}C in monsoon, 26.2^{0}C in post monsoon, 28.5^{0}C in summer (Table 1). The two way Anova showed no significant variation between sites (P>0.05) and significance variation between seasons (P<0.05) (Table 2). The soil pH in agricultural land was an average of 5.8 in pre monsoon, 5.8 in monsoon, 5.8 in post monsoon, 5.8 in summer (Table 1).The agricultural habitat was acidic in nature. The two way Anova showed the pH of the soil have no significant variation between sites (P>0.05) and showed significance variation between seasons (P<0.05) (Table 2). The moisture content in agricultural habitat was an average of 77% in pre monsoon, 89% in monsoon, 82% in post monsoon, and 76% in summer (Table 1). The two way Anova showed the moisture content have no significant variation between sites (P>0.05) and showed significance variation between seasons (P<0.05) (Table 2).

The organic carbon content in agricultural habitat was an average of 2.73% in pre monsoon, 2.82% in monsoon, 2.79% in post monsoon, and 2.83% in summer (Table 1). The two way Anova showed the organic carbon content have no significant variation between sites (P>0.05) and showed significance variation between seasons (P<0.05) (Table2).The exchangeable acid in agricultural habitat was an average of 81% in pre monsoon, 82% in monsoon, 81% in post monsoon, 83% in summer (Table 1). The two way Anova showed the exchangeable acid content in agricultural soil have no significant variation between sites (P>0.05) and showed significance variation between seasons (P<0.05) (Table2). The exchangeable base in agricultural habitat was an average of 20% in pre monsoon, 16% in monsoon, 19% in post monsoon, 18% in summer (Table 1). The two way Anova showed the exchangeable base content in agricultural soil have no significant variation between sites (P>0.05) and showed significance variation between seasons (P<0.05) (Table 2).

The sand content in agricultural habitat was an average of 9% in all seasons. The silt content was an average between 0.13% and 0.18%. The clay content was an average between 14 % and 18% was showed good porosity (Table 1). The two way Anova showed the sand content have no significant variation between sites and seasons (P>0.05) (Table2). The two way Anova showed the silt and clay content have no significant variation between sites (P>0.05) and showed significance variation between seasons (P<0.05) (Table 2).

The phosphorus content was an average of 10.24 ppm in pre monsoon, 9.39 ppm in monsoon, 9.71 ppm in post monsoon, 9.27 ppm in summer. The potassium content was an average of 144.2 ppm in pre monsoon, 123.4 ppm in monsoon, 137.06 ppm in post monsoon, 136.7 ppm in summer (Table3). The two way Anova showed the nitrogen, phosphorus and potassium content have no significant variation between sites (P>0.05) and showed significance variation between seasons (P<0.05) (Table 4). The calcium content in agricultural habitat was an average of 695.07 ppm in pre monsoon, 684.93 ppm in monsoon, 689.13 ppm in post monsoon, 681.83 ppm in summer. The magnesium content in agricultural habitat was an average of 163.98 ppm in pre monsoon, 137.62 ppm in monsoon, 141.72 ppm in post monsoon, 155.03 ppm in summer (Table3). The two way Anova showed the calcium and magnesium content have no significant variation between sites (P>0.05) and showed significance variation between seasons (P<0.05) (Table 4)

3.2 Grassland habitat

3.2.1 Soil edaphic factors

In grass land habitat the soil edaphic factors like soil temperature, pH, exchangeable acid, exchangeable base, organic carbon content, moisture content, sand, silt, and clay content were detected.

Soil temperature in grass land was at an average of 27.3^0C in pre monsoon,23.5^0 C in monsoon, 26.9^0C in post monsoon,27.9^0C in summer (Table 5).The two way Anova showed no significant variation between sites (P>0.05) and significance variation between seasons (P<0.05) (Table 6). The soil pH in grass land was an average of 6.5 in pre monsoon, 6.36 in monsoon, 6.4 in post monsoon, and 6.4 in summer (Table 5). The agricultural habitat was acidic in nature. The two way Anova showed the pH have no significant variation between sites (P>0.05) and showed significance variation between seasons (P<0.05) (Table 6). The moisture content in grass habitat was an average of 76% in pre monsoon, 84% in monsoon, 78% in post monsoon, and 71% in summer (Table 5). The two way Anova showed the moisture content have no significant variation between sites (P>0.05) and showed significance variation between seasons (P<0.05) (Table 6). The organic carbon content in grassland habitat was an average of 4.50 in pre monsoon, 4.55 in monsoon, 4.54 in post monsoon, and 4.41 in summer (Table 5). The two way Anova showed the organic carbon content have no significant variation between sites (P>0.05) and showed significance variation between seasons (P<0.05) (Table 6).

The exchangeable acid in grass land habitat was an average of 83% in pre monsoon, 71% in monsoon, 75% in post monsoon, and 77% in summer (Table 5). The exchangeable base in grass land was an average of 19% in pre monsoon, 18% in monsoon, 14% in post monsoon, 13% in summer (Table 5). The two way Anova showed the exchangeable acid and exchangeable base content in grass land soil have no significant variation between sites (P>0.05) and showed significance variation between seasons (P<0.05) (Table 6). The sand content in agricultural habitat was an average of 7% in all seasons. The silt content was an average between 0.54% and 0.85%. The clay content was an average between 25% and 27%. The two way Anova showed the silt and clay content have no significant variation between sites (P>0.05) and showed significance variation between seasons (P<0.05) (Table 6).

Table 5: Soil edaphic factors of grass land at different seasons (Mean ± SD)

Season		pH	Moisture (%)	OC%	EA%	EB%	Sand%	Silt%	Clay%

3.2.2Soil chemical factors

In grass land habitat soil chemical factors like nitrogen, phosphorus, potassium, calcium and magnesium were analyzed. The nitrogen content in grass land habitat was an average of 1032.4ppm in pre monsoon, 1022.3ppm in monsoon, 1020.73ppm in post monsoon, 1031.2ppm in summer. The phosphorus content was an average of 4.61ppm in pre monsoon, 4.87ppm in monsoon, 4.48ppm in post monsoon, 4.73ppm in summer. The potassium content was an average of 116.7ppm in pre monsoon, 111.1ppm in monsoon, 118.53ppm in post monsoon, 113.53ppm in summer (Table 7). The two way Anova showed the NPK content have no significant variation between sites (P>0.05) and showed significance variation between seasons (P<0.05) (Table 8).

The calcium content in grass land habitat was an average of 1549.34ppm in pre monsoon, 1538.83ppm in monsoon, 1564.43 ppm in post monsoon, 1542.17ppm in summer. The magnesium content in grass land habitat was an average of 288.85ppm in pre monsoon, 286.97 ppm in monsoon, 284.11 ppm in post monsoon, 292.84ppm in summer (Table 7). The two way Anova showed the calcium content have no significant variation between sites and seasons (P>0.05) (Table 8), but in magnesium content have no significant variation between sites (P>0.05) and showed significance variation between seasons (P<0.05) (Table 8).

Table 7: Soil chemical factors of grassland at different seasons (Mean±SD)

Season	Nitrogen (ppm)	Phosphorus (ppm)	Potassium (ppm)	Calcium (ppm)	Magnesium (ppm)

	Between season	533.66	2.960351	$3.91X10^{-24}$

4. Discussion

From agricultural habitat and grass land habitat soil edaphic factors were analyzed. Soil edaphic factors like soil temperature, pH, exchangeable acid, exchangeable base, organic carbon content, moisture content, sand silt, and clay content were detected. The temperature influences the fertility of the soil, if the temperature increases the decomposition of organic matter increases. The grass land habitat showed an optimum range of temperature. Environmental factors, can affect soil pH, the p^H ranges showed that the two habitats were acidic in nature. The plants and soil life forms prefer either alkaline or the acidic nature of the soil. pH can also affect the availability of nutrients in the soil. The organic carbon content was more in grass land than agricultural land. The agricultural land was sandy in nature, leaching is active in sandy soils. The clay content was more in grass land habitat.The clay content and organic matter, which influence the exchange capacity of the soil.

The soil chemical factors like nitrogen, phosphorus, potassium, calcium and magnesium contents were analyzed. Nutrient balance is very important in soil habitat. The mobility of nutrients within the soil is closely related to the chemical properties of the soil. The present study showed the agricultural habitat soil had high amount of nitrogen, phosphorus, potassium. The very high level of nitrogen and phosphorus content in the agriculture land is due to the application of chemical fertilizers during agricultural activity (Thomas, 1994). Phosphorus, nitrogen and potassium, contents are very essential for the normal growth of plants. The magnesium and calcium content were more in the grass land habitat. The high availability of magnesium and calcium contributes the low survival of higher plants in grass land (Sankar, 1996). Low soil magnesium levels will affect grass yield as well as mineral balance in the animal.

4 Summary and Conclusion

Compared the agricultural habitat and grass land habitat based on the soil edaphic factors like soil temperature, pH, exchangeable acid, exchangeable base, organic carbon content, moisture content, sand silt, and clay content, soil chemical factors like nitrogen, phosphorus, potassium, calcium and magnesium content. In each habitat 10 sites were selected for the soil study. Soil samples were taken from each study site monthly during pre monsoon, monsoon, and post monsoon and summer seasons. Mean with standard deviation were taken for each parameter value. Two way ANOVA was conducted to test whether the samples have variation in values between sites and seasons. From this study found that the grass land habitat was more fertile than the agricultural habitat.
