Abstract: Cloud computing has generated a lot of interest and competition in the industry and it is recognize as one of the top 10 technologies . It is an internet based service delivery model which provides internet based services, computing and storage for users in all market including financial, health care & government. In this paper we did systematic review on different types of clouds and the security challenges that should be solved. Cloud security is becoming a key differentiator and competitive edge between cloud providers. This paper discusses the security issues arising in different type of clouds.

Keywords: Cloud, Security, Security challenges, Cloud computing

1. Introduction

The term “cloud” was coined from the computer network diagrams which uses it to hide the complexity of infrastructure involved. cloud computing provides software, platform and infrastructure as a service. its main features include resource pooling, rapid elasticity, measured service, on-demand self service and broad network access. so, a cloud is a collection of hardware and software that runs in a data centre and enables the cloud computing model. A cloud reduces capital investment, hardware cost and software licence cost. cloud computing also raises severe challenges especially regarding the security level required for the secure use of services provided by it. There are no publically available standards specific to cloud computing security. so, in this paper, we propose the following standards for maintaining security in an unsafe cloud computing environment.

Main Characteristics Include;

- **On-demand self-service:** The ability for an end user to sign up and receive services without the long delays that have characterized traditional IT.
- **Broad network access:** Ability to access the service via standard platforms (desktop, laptop, mobile etc).
- **Resource pooling:** Resources are pooled across multiple customers.
- **Rapid elasticity:** Capability can scale to cope with demand peaks.
- **Measured Service:** Billing is metered and delivered as a utility service

Three distinct categories within Cloud Computing:

- 1) Software as a Service,
- 2) Platform as a Service and
- 3) Infrastructure as a Service.

SaaS applications are designed for end-users, delivered over the web.

PaaS is the set of tools and services designed to make coding and deploying those applications quick and efficient.

IaaS is the hardware and software that powers it all

– servers, storage, networks, operating systems

Characteristics of SAAS

- Web access to commercial software.
- Software is managed from a central location.
- Software delivered in a “one to many” model.
- Users not required to handle software upgrades and patches.
- Application Programming Interfaces (APIs) allow for integration between different pieces of software.

Characteristics of PAAS

- Services to develop, test, deploy, host and maintain applications in the same integrated development environment. All the varying services needed to fulfil the application development process .
- Web based user interface creation tools help to create, modify, test and deploy different UI scenarios.
- Multi-tenant architecture where multiple concurrent users utilize the same development application.
- Built in scalability of deployed software including load balancing and failover
- Integration with web services and databases via common standards.
- Support for development team collaboration – some PaaS solutions include project planning and communication tools.
- Tools to handle billing and subscription management

Characteristics of IAAS

- Resources are distributed as a service.
- Allows for dynamic scaling.
- Has a variable cost, utility pricing model.
- Generally includes multiple users on a single piece of hardware.

2. Various Types of Clouds

Clouds are broadly classified as:

Volume 4 Issue 5, May 2015

www.ijsr.net

Personal Clouds:

Such clouds are especially operated by single organization.

General Clouds:

These clouds are used for providing services to common people.

Domain-Specific Clouds:

These clouds are maintained for specific requirements by a group of organizations

Mixed Clouds

Personal clouds: are used to provide a broad range of office and enterprise computing services. It involves applications for online collaboration, email and calendaring such as ERP software. Conventional approaches to computing have constraint our ability to meet the needs. For example, in traditional computing servers are dedicated to specific applications. This results in poor utilization of server. So, personal clouds provide a new architecture for improving efficiency. It includes a hosting platform, interfacing unit and infrastructure services. By building a personal cloud, we can deliver the benefits of public cloud without incurring the risk for the data and application.

These clouds are a mixture of above said three clouds which can share data to achieve fulfil a specific requirement. General Cloud: A general cloud in which a service provider makes resources such as applications and storage is available to the general public over the internet. The main advantages of using general cloud services are:

- Easy and inexpensive setup because hardware, application and bandwidth costs are covered by the provider.
- Scalability to meet needs.
- Economic for general public.

There are shared infrastructures and services in general cloud which may give rise to new security issues. The following security challenges are yet to be solved where the attacker or hacker needs to be hurdled:

- Placing malicious code on the physical machine.
- Attack on VM (Virtual Machine) from other VMs.
- DoS Attacks

Domain Specific clouds: In the past few years, security investment was largely driven by regulatory mandates. for example payment card industry, data security standards mandates regular vulnerability scanning of IT assests, retail and financial services organization purchased scanning and log management tools. Mount Sinai Hospital in Torento is building a community cloud in conjunction with the Canadian govt. that will give 14 areas hospitals shared access to a fatal ultrasound application and data storage for patient information. Security Issues in Domain Specefic:

- Compliance and auditing
- Intrusion Detection (IDS) and Firewall features.
- Access control
- Anti Virus/Anti Malware protection

Hybrid Clouds

A hybrid cloud is a combination of at least one private cloud and at least one general cloud. It is a cloud computing

environment in which an organization provides and manages resources internally and externally. It allows a business to take advantage of the scalability and cost effectiveness.

- Risk of multiple cloud tenants.
- Ongoing compliance concerns
- Access control and identity management.
- Data slinging

3. Security Model for IAAS

The security model for IaaS (SMI) as a guide for assessing SMI model consists of three sides: IaaS components, security model, and the restriction level

4. Cloud Computing Models

Public cloud

A public cloud is one based on the standard cloud computing model, in which a service provider makes resources, such as applications and storage ,available to the general public through the internet.public cloud services may be free on a pay-per-usage model.

Community cloud

Private cloud (also called internal cloud or corporate cloud) is a marketing term for a proprietary computing architecture that provides hosted services to a limited number of people behind a firewall.

Private Cloud

A community cloud may be established where several organizations have similar requirements and seek to share infrastructure so as to realize some of the benefits of cloud computing. With the costs spread over fewer users than public cloud

5. Conclusions

In this paper much of the work has been focused on types of clouds and their security challenges and it describes the way of designing the solution for the security threats. It gives a comparison between different services providers on different cloud services SaaS, PaaS, IaaS. This review shows that there are several types of clouds and the related security

challenges on each level. It also includes about various layers of infrastructure as a service. Security issues presented here concern the security of each IaaS component in addition to recent proposed solutions.
