Abstract: A well planned and selected diet can reduce or eliminate symptoms of heart burn and esophageal erosions. This study analysed nutrient content of a strict diet on relieving gastro esophageal symptoms caused by excessive production of gastric acid. The food tests were carried out to establish the amounts of nutrients (vitamins, mineral elements, proteins, fats and carbohydrates) which were available in the breakfast, lunch and supper. This study established that the nutrients in the diet were provided in adequate amounts. The nutrient-nutrient interaction was also recognised.

Keywords: Homeostatic, heartburn, nutrient-nutrient interaction

1. Introduction

Heartburn is the backward flow or regurgitation of stomach contents passing up into the esophagus resulting in acid erosion of the esophagus [1]. Certain foods contain nutrients that help eliminate or reduce heartburn. A balanced diet maintains healthy body systems and alleviates heartburn. Some of the symptoms associated with heartburn include hoarseness of voice, persistent need for clearing of the throat, excess throat mucus of postnatal drip, coughing after eating or lying down, breathing difficulties or choking episodes, troublesome or annoying cough, sensation of something sticking in the throat, heart, chest pain, indigestion or stomach acids[2].

All these symptoms can be relieved by a diet containing antioxidants. Some of the antioxidants include fat soluble vitamins (ADEK) in addition to water soluble vitamin C[3]. Some antibacterial chemicals contained in onion, pistachio nuts, ginger, origano and thyme that are used when preparing meals destroy bacteria that are responsible for producing toxins associated with heartburn[4].

Onions have a chemical (quercetin) that relieves cough, asthma, and some associated chest pains. The onion mineral salts are converted to carbonates which are alkaline, and when absorbed in the circulation system have a buffering effect of maintaining an optimum blood pH. Onions are also known to reduce blood glucose level and they contain enzymatic substances such as polyphenol oxidase and diastase which are beneficial for the digestive system. Onions contain sulphur which is required for the synthesis of essential fatty acids. These fatty acids are known to break down heavy mucus thereby facilitating expeoration of bronchial secretions. Ginger is good for digestion for the quick movement of the food through the digestive system [5].

Okra is rich in soluble mucilage fibre which is good for a protective and emollient function within the digestive system [6]. Okra is a rich source of vitamin A, vitamin C, and vitamin B group except B12. Okra is rich in mineral salts such as calcium, magnesium, iron, potassium and sodium. Okra is good for relieving stomach ulcer, throat, and bronchitis. Okra has an alkalizing effect to the blood because of its mineral salts.

Spinach is rich in vitamins and minerals [7]. It contains lutein and zeaxanthin, antioxidants that protects the retina of the eye. Spinach is good for iron deficiency anaemia. Spinach protein reduces the absorption of cholesterol and bile acids.

Lettuce is a remedy for obesity because of its ability to satisfy appetite. It is rich in vitamins and minerals[8] and has a sedative and sleep inducing substance that are not toxic. Lettuce improves digestion when eaten before a meal and is very low in carbohydrate making it suitable for people who are overweight and diabetic.

Broccoli is a rich source of vitamins and minerals [9]. Broccoli also contains anticarcinogenic phytochemicals. It is suitable for people who are obese and diabetic, because it has low calories, and it produces a certain feeling of satiety. Broccoli contains antibiotics that destroys Helicobacter-Pylori.

Lemon when mixed in the mouth with starchy foods, such as chestnut, potatoes, or bananas is useful in weightreduction. The acid in lemon inhibits the action of ptyalin, an enzyme in saliva that initiates carbohydrate digestion in the mouth [10]. Lemons contain phytochemicals which prevent cancer and other diseases the greatest achievement of advanced nutrition science. Lemon contains organic acids, such as citric acid, formic acid, ascorbic acid, which have antiseptic effects. Flavonoids in lemon serve as antioxidants potentiating vitamin C. The antioxidants neutralizes free
radicals, prevent cell damage, and also relieve heartburn and associated symptoms.

Various minerals in the body have diverse functions [11]. Phosphorus is required in the generation of bony tissue, the metabolism of glucose and lipids and regulation of acid base balance. Calcium’s role in body homeostasis includes participation in the transmission of nerve impulses and muscle contractions. Sodium and potassium ions are of utmost importance. The presence of these ions around biological membranes leads to the formation of electric potentials which are essential for life function. Sodium and potassium ions utilise 30 to 70% of all ATP produced in the body [12].

In this paper the nutrient composition and nutrient-nutrient interaction for the prescribed heartburn diet is explored. Previous work by Wu et al [13] reported the use of strict diet in providing adequate mineral salts to maintain homeostatic mechanism especially acid base balanceto heartburn sufferers. In our previously work,a strict diet was administered to several patients and its positive effects were reported [14].

2. Method

2.1 Moisture Content

About 3.0 g food samples from the diet prescribed for breakfast, lunch and supper were separately weighed on an analytical balance and transferred into crucibles. The samples were dried for 12 h in an oven set at 50°C. The dried samples were ground, reweighed and redried until constant mass was attained. The samples were cooled and stored in a desiccator. The percentage moisture content was calculated using Equation 1.

\[
\text{Moisture content(%) } = \frac{\text{weight of dried sample} \times 100}{\text{weight of original sample}} \quad (1)
\]

2.2 Crude Fibre Content

Crude fibre was determined following Weende method [15]. Solid food samples (3 g) were weighed into pyrex crucibles. The samples were then transferred to the boiling position in the hot extraction unit (Fibertec system 1). To each sample, 150 ml of 1.25% sulphuric acid preheated on a hot plate was added. This was followed by addition of 2-3 drops of n-octanol to prevent foaming, and the mixtures were gently boiled for 30 minutes. Any sediments formed were filtered by applying reverse pressure. The fibres were washed thrice with hot deionised water (50 mL each wash) using the spray device from the top of the boiling tubes. The water was sucked to leave fibre as dry as possible. To each sample 150 ml of 1.25% NaOH solution, preheated on a hot plate was added. This was followed by addition of 2-3 drops of n-octanol to prevent foaming, and the mixtures were gently boiled for 30 minutes. Any sediment formed were filtered by applying reverse pressure. The fibres were washed thrice with hot deionised water (50 mL each wash) using the spray device from the top of the boiling tubes. The samples were transferred to the cold extraction unit, washed three times with acetone (about 25 mL each time) and vacuum dried. The samples in crucibles were removed, dried in oven at 130°C for 2 h. The crucibles were cooled in a desiccator and weighed. The weighed samples were ashed in a muffle furnace at 550°C for 3 hours. The ashed samples were cooled to room temperature and weighed. The percentage ash content was determined according to Equation 2.

\[
\text{Crude fibre(%) } = \frac{\text{weight of ashed sample} - \text{weight of dried sample}}{\text{weight of original sample}} \times 100 \quad (2)
\]

2.3 Crude Fat Content

Approximately 3.0 g samples were transferred into 25 mL round bottomed flasks containing 150 ml petroleum ether. The samples were extracted in a soxhlet extractor for approximately 4-6 h before removing the extracted fat using a rotary evaporator. Any excess solvent in sample flasks was removed in an oven (105°C) for 30 minutes. The samples were placed in desiccators, cooled and weighed. Crude fat weight was determined according to Equation 3.

\[
\text{Crude fat(%) } = \frac{\text{weight of extracted fat \times 100}}{\text{original mass of sample}} \quad (3)
\]

2.4 Ash Content

Milled food samples (1 g) in crucibles were placed on a hot plate and heated until there was no smoking. The crucibles were placed in a Muffle furnace (550°C) for 3 hours. The crucibles were cooled to room temperature in a desiccator and the weight of ash determined (Equation 4).

\[
\text{Ash content(%) } = \frac{\text{weight of asched sample} \times 100}{\text{weight of original sample}} \quad (4)
\]

2.5 Mineral Content

The mineral content in food samples were determined by atomic absorption spectrometer (Perkin-Elmer Model 214) following AOAC 999-10 international method of 2012 [16].

2.6 Vitamin Content

Vitamins were analysed using high performance liquid chromatography (Shimadzu LC-10AVP). The standards were prepared by weighing 15 mg of each vitamin powder and dissolving in methanol making stock solutions of 1.0 mg/mL in volumetric flasks.

Fat soluble vitamins were extracted from 0.125g of grounded samples and placed in 10ml volumetric flasks containing 8ml of dichloroethanol. After 15 min of ultrasonication extraction dichloroethanolic acid was added (1:1) and the mixture stored in the dark.

Ground water soluble vitamin samples (0.125 g) were added to 8 mL of water in 100 mL volumetric flask. After 15 min of ultrasonication extraction a further 8 mL of water was added.

Water and fat soluble vitamins were then injected into HPLC. Prior to injection each solution was filtered through 0.2 µm filter. Samples (20 µL) were injected at 25°C and 1.0 mL/min flow rates. Vitamins A was analysed using...
important for prevention of diseases. Proteins and carbohydrates in the diet. Vitamins and minerals are nutrients such as minerals, vitamins, proteins and amounts of solid foods. Ash shows that there are other than breakfast (4.42%) since these two meals contain higher Lunch and supper contains high ash content (at least 6%) development and the formation of healthy cell membranes. Synthesis of steroid hormones. Fats and oils help with cellular Metabolic fats such as cholesterol are important for the and vegetables have invisible fats found inside cell structures. Fruits contains fats and oils which are essential for the body. Fruits and vegetables are stored in the liver and the body tissues [20]. These vitamins are generally not affected by cooking or storage and are more heat and light stable. Vitamin B forms several complexes. Pantothenic acid oxidized fats carbohydrates some amino acids, pantothenic forms part of a compound called acyl carrier protein. This protein attaches to fatty acids and shuttles them through the metabolic pathway to increase their chain length. Also a co enzyme A, donates fatty acids to proteins determines the location and function within the cell. Pyridoxine another vitamin B complex is essential for protein, carbohydrate metabolism and the formation of red blood cells, also it maintains nervous and immune system. Pyridoxine plays an enzyme role in more than 100 enzymatic reactions. Vitamin B6 is responsible for DNA synthesis, normal cell division and for interconversion of amino acids (homocysteine, methionine). All forms of folate are converted to basic co enzyme form tetrahydrofolic acids, formation of neurotransmitters in the brain. Folate also was responsible in the elimination of shortness of breath as a symptom of heartburn. Folate is a co enzyme in the single-carbonyl in protein and carbohydrate metabolism. Folacin (vitamin B9) is responsible for production of red blood cells. Cobalamine (vitamin B12) is also responsible for formation of red blood cells, prevention of megaloblastic anemia and function of nervous system. Cobalamine is responsible for formation of co enzyme in the intermediary metabolism. It is important for neurotransmitter such as dopamine, serotonin, norepinephrine (noradrenaline) tryptamine, histamine and taurine for the normal function of the brain [21].

#### 3.2 Vitamin Content

Figures 1 and 2 show daily vitamin intake from the strict diet. The daily amounts of vitamins provided by the diet were adequate as compared to the quantities stipulated by WHO [19]. The daily WHO vitamin specifications were lower than those provided by the strict diet. Vitamins supplied from the diet cannot be in excess since they are converted to other forms. One such example is the conversion of vitamin A to its retinol equivalence.

Vitamins are essential micro nutrients that are required by the body in small amounts for various functions therefore must be provided by the diet. Fat soluble vitamins ADEK are stored in the liver and the body tissues. Vitamin B complex is essential for protein, carbohydrate metabolism and the formation of red blood cells, also it maintains nervous and immune system. Pyridoxine plays an enzyme role in more than 100 enzymatic reactions. Vitamin B6 is responsible for DNA synthesis, normal cell division and for interconversion of amino acids (homocysteine, methionine). All forms of folate are converted to basic co enzyme form tetrahydrofolic acids, formation of neurotransmitters in the brain. Folate also was responsible in the elimination of shortness of breath as a symptom of heartburn. Folate is a co enzyme in the single-carbonyl in protein and carbohydrate metabolism. Folacin (vitamin B9) is responsible for production of red blood cells. Cobalamine (vitamin B12) is also responsible for formation of red blood cells, prevention of megaloblastic anemia and function of nervous system. Cobalamine is responsible for formation of co enzyme in the intermediary metabolism. It is important for neurotransmitter such as dopamine, serotonin, norepinephrine (noradrenaline) tryptamine, histamine and taurine for the normal function of the brain [21].

Vitamin A, good for growth, health of the body, good vision, cornea maintenance, and resistance to infection. Maintain white and red blood cell membrane. Protect regeneration of cells and mucous membrane as well as maintenance of healthy respiratory and intestinal tract together with folate vitamin A eliminates some symptoms of heartburn. Vitamin A maintains epithelial tissues /cells. Essential for immune functions for blood cells as T-lymphocytes and killer cells which play a critical role in the defense against pathogens[21]. Vitamin A has other metabolic uses such as maintenance of bone growth, for spermatogenesis, and for mucopolysaccharide synthesis. Vitamin A from the diet can not cause toxicity because it has to be converted to retinol for example β-carotene to retinol the ratio is12µ β-carotene=1µ retinol and conversion depends on food matrix, presents of dietary fat efficiency of absorption and health of the subject.

Vitamin E is essential for reproductive, muscular, circulation, nervous and immune system [22]. The fat soluble antioxidant that helps maintain cell membrane, red blood cell integrity, protects vitamin A and fatty acids from oxidation. It also prevents peroxidative damage of cell membranes, in the mitochondria. Circulation and respiratory oxidation. It also prevents peroxidative damage of cell membranes and red blood cell integrity, protects vitamin A and fatty acids from oxidation. It also prevents peroxidative damage of cell membranes and protective function in the immune system.

Figure 1: Daily vitamin intake

3.3 Mineral Content

The mineral content of meals taken for breakfast, lunch and supper are shown in Table 2. The mineral nutrient levels fall within the recommended daily intake.

Potassium, a primary electrolyte in the body fluids, its main roles are fluid balance, nerve impulse transmission, influences the contractility of smooth, skeletal and cardiac muscles. It was supplied from the diet mainly from pawpaw, avocado, fish, brown rice, egg and chicken. Potassium is the major cation inside cells. Intra–cellular fluids contain 95% of potassium in the body [23]. The outstanding importance of potassium for the maintenance of body is its ability to mobilise alkaline calcium salts from bone in order to neutralise acids consumed in the diet and generated by metabolism [24]. There are two major body fluid compartments namely extracellular and intracellular. The compartments are further divided into interstitial fluid and plasma components as is shown in Fig. 3[25].

The main sources of magnesium from the diet were spinach, avocado, oats, brown rice and spaghetti. Magnesium is vital for biochemical and physiological homeostasis processes. Magnesium is useful for enzymes that utilize ATP to form active ATP. It is important for nerve and heart function, as well as for insulin release from the pancreas and ultimate insulin action in the cells [26].

Fish, spinach, broccoli, oats, eggs milk and milk products were the main sources of calcium in the diet. Calcium is useful for blood clot, bone forming, and metabolism of proteins. Calcium works together with adequate Vitamin C and vitamin D to maintain homeostasis or body systems. Calcium is necessary for nerve transmission, muscle contraction, glandular secretion and the contraction and dilation of the blood vessels [27].

The major sources of phosphorous from the strict diet were eggs, fish, broccoli, brown rice, chicken, milk and milk products. Phosphorous is a component of membrane phosphorous lipids, nucleotides and nucleic acids, and a component of bones and teeth. It functions to buffer body fluids to maintain a normal pH, thereby eliminating some of the heart burn symptoms especially chest pain, indigestion and stomach acid that come up to the esophagus [28]. It stores and transfers energy derived from metabolic fuels for a short time.

The main sources of iron from the strict diet are eggs, spinach and brown rice. Iron plays an important role in the human body with the aid of vitamin C. The most important group of iron-binding proteins contains the heme units, which contain iron at their central metal ion. Redox reactions and electron transport processes that occur in humans make use of heme proteins[29]these reactions are needed for oxidative phosphorylation, the principal source of energy for human cells.

4. Conclusion

This study has demonstrated that the nutrients provided by the strict diet were in adequate proportions. The nutrients in the diet help to reduce or eliminate heartburn and associated symptoms through their interactions in the body metabolic processes. Some of the nutrients neutralized the stomach and blood acids that were produced during digestion and metabolism. The proteins, fats and carbohydrate content were in adequate amounts to ensure normal function of the body system. Heartburn sufferers are recommended to adopt the prescribed diet.
