Abstract: **Aim:** To see the difference between salivary cortisol values, correlation with the work stress, and the difference between salivary and cortisol values related to sex. **Methods:** The salivary and serum cortisol values were analyzed in two groups of nurses, six nurses in the Emergency Department and six nurses in the Pathology Department at our hospital, three females and three males for each group. The samples were taken before beginning the work and after finishing the work. **Results:** Mean serum and salivary cortisol values in the morning (08:00 AM) and at the end of the work (04:00 PM), were higher in Emergency Department compare to the mean salivary and serum values of cortisol in the Pathology Department. The salivary and serum cortisol values were higher in males compared to females, but are not statistically significant. **Conclusions:** Since the work stress is higher in the Emergency Department, even the results of the salivary cortisol values were higher in the nurses of the Emergency Department compared to the nurses of Pathology Department and there existed a correlation between salivary and serum values, but we needed a bigger group of study to have more trustful conclusions.

Keywords: salivary cortisol, serum cortisol, correlation, work stress

1. Introduction

Cortisol is a major glucocorticoid produced in the adrenal cortex and used in studies of the pituitary adrenal axis function. More than 90% of cortisol is bound to serum proteins [1]. The measuring of cortisol is performed in blood or urine, but in the last years the measuring of the salivary cortisol is also used in the clinical practice [2]-[5]. The collection of the sample in the saliva can be done by the individuals themselves, whom are being analyzed, respecting some simple instructions. It is a non-invasive, painless and stress-free procedure [6]. Salivary cortisol levels are relatively resistant to degradation from enzymes or freeze-thaw cycles [7].

2. Methods

The salivary and serum cortisol values were analyzed in two groups of nurses, six nurses working in the Emergency Department and six nurses working in the Pathology Department at our hospital, three females and three males for each group (total six females and six males). All the participants in the study were informed about the study protocol and its aim. They were in a young age, without any know acute or chronic diseases, norm weight. The participants were not taking any treatment with substituting medicine or medicines which interfered with the cortisol metabolism. They didn’t consume more than a glass of wine or its equivalents per day, they didn’t smoke, the coffee consumers didn’t use more than two cups of coffee per day. All the participants filled questioners, which was prepared and approved before. The day of the blood and saliva samples collection, anthropometric measurements, blood pressure, heart rate and body temperature were measured. The subjects shouldn’t have passed a febrile condition or be in such a condition at least two weeks before the collection of the blood and saliva samples.

All the subjects followed the rules for the collection of the saliva. The saliva was collected by the participants in the study themselves. Before the collection of the saliva sample, the participants should respect some rules:

- The use of the alcohol was forbidden for 12 hours until the collection of the saliva.
- The subjects must have been not eaten for at least one hour before the collection of the saliva sample.
- The use of the toothbrush was not allowed for at least 45-60 minutes before the collection of the saliva sample.
- The use of the sweet and caffeine-containing beverages, coffee and milk products were forbidden for at least 20 minutes before the collection of the saliva sample.
- At first the mouth was rinsed with water and after 10 minutes the saliva sample was collected.

The samples of saliva and serum were collected in the morning at 8:00 AM and in the afternoon at 4:00 PM (before work and after work).

- At the same time of the collection of the saliva samples, there were also collected the blood samples for measuring the serum cortisol. After the collection of the saliva, the samples were stored in 4° Celsius for eight hours and then they were kept frozen in –20° Celsius until the moment of the analysis and then they were centrifuged for 10 minutes in 3000 rpm.
- The samples for the serum cortisol were obtained from the antecubital vein. The samples were stored in room
temperature for 20 minutes, and then they were centrifuged for 5 minutes in 3000 rpm and were kept in –20° Celsius until the moment of the analysis.

3. Materials and Methods

12 healthy nurses (6 males and 6 females), ages from 22-30 years old, were included in the study. The blood and saliva samples were collected in the morning at 8:00 AM and in the afternoon at 4:00 PM after work. All the participants in the study respected the rules of saliva samples collection. 6 nurses (3 females and 3 males) worked at emergency department and 6 nurses (3 females and 3 males) worked at pathology department.

3.1 Laboratory Analyses

Serum cortisol was measured by RIA CT AcM and salivary cortisol was determined by Salivary Cortisol ELISA kit.

3.2 Statistical Analyses

The data were presented as mean (SD). The relation between variables was expressed as correlation coefficients – Pearson’s coefficients. P-level < 0.05 was considered as statistically significant.

4. Results

Mean serum cortisol values in the Emergency Department in the morning (8:00 AM) were 188 ± 30 ng/ml (normal range 55–230) and mean salivary cortisol values 3.1 ± 1.4 μg/dl (normal range 1–11.3) and at the end of work (4:00 PM) the values were: serum cortisol values 130 ± 28 ng/ml (normal range 28–140) and salivary cortisol values 1.87 ± 0.5 μg/dl (normal range 0.2–2.7). In the Pathology Department: in the morning (8:00 AM) mean serum cortisol values were 125 ± 22 ng/ml and salivary cortisol values 2.1 ± 1.1 μg/dl and at the end of the work (4:00 PM): mean serum cortisol values were 94.0 ± 16.5 ng/ml and salivary cortisol values 1.22 ± 0.2 μg/dl. Mean weight of participants was 66.5 kg ± 10 SD, mean BMI (body mass index) was 23.2 kg/m², mean blood pressure was 107/66 mmHg and mean heart rate was 73/min ± 5.8 SD. All the subjects had normal body temperature.

We found correlation between serum and salivary cortisol values at the beginning of the work and after finishing the work, at the emergency and pathology cortisol values, correlation coefficient r = 0.4, and the values of salivary and serum cortisol values were higher at the emergency department compared to pathology department, but wasn’t statistically significant (Table no 1).

We found correlation between serum and salivary cortisol values at the beginning of the work and after finishing the work, at the emergency and pathology cortisol values, correlation coefficient r = 0.4, and the values of salivary and serum cortisol values were higher at the emergency department compared to pathology department, but wasn’t statistically significant (Table no 1).

We found correlation between serum and salivary cortisol values at the beginning of the work and after finishing the work, at the emergency and pathology cortisol values, correlation coefficient r = 0.4, and the values of salivary and serum cortisol values were higher at the emergency department compared to pathology department, but wasn’t statistically significant (Table no 1).

The serum and salivary cortisol values of cortisol of males in our study were higher compared with females’ values, but sex differences in salivary and serum cortisol values among nurses weren’t statistically significant and we didn’t found a correlation (r = -0.1; p >0.05 ).
5. Discussions

Previous studies have also indicated that cortisol levels differ between men and women [8]-[11], [12]-[14]. In our study, we noticed higher levels of salivary and serum cortisol values in the nurses working in the emergency department, compared to the nurses working in the pathology department. But our study had some limitations: first, the number of participants, which was small and we needed to perform the study in a bigger group of nurses, to have more trustful conclusions; second, we know that in the emergency department the work is more intensive and there is the need to work quickly, but we did not use any indicator to measure the level of stress at the nurses in both groups, the emergency and the pathology department.

6. Conclusions

Mean salivary and serum cortisol values were higher in males compared to females, but are not statistically significant. Since the stress of work is higher in the Emergency Department, even the results of the salivary cortisol values were higher in the nurses of the Emergency Department compared to the nurses of Pathology Department and there existed a correlation between salivary and serum values, which wasn’t statistically significant (p> 0.05), but the study needed a bigger group of nurses to have more trustful conclusions.
