Effect of rs2241766T>G polymorphism in Adiponectin Gene on Circulating Adiponectin Levels among Iraqi Women with PCOS

Rasha Shaker Nima

Department of Chemistry, College of Science, University of Kufa

Abstract: Background: Polycystic ovary syndrome (PCOS) is a most common endocrine/metabolic disorder of women in their reproductive ages. Although PCOS is complex, but there is strong evidence that candidate genes on insulin action have been proposed to show a vital role in its etiology. Aim: The current research was designed to study the effect of (rs2241766T>G) in adiponectin gene with PCOS, and their impact on the level of serum adiponectinand insulin resistance (HOMA-IR) in Iraqi women with PCOS. Methods: The case –control design study was performed on 120 women with and without PCOS. Phenotypic analysis included the estimation of fasting levels of: blood glucose, and lipid profile by spectrophotometric methods, while insulin, and adiponectin concentrations were determined by ELISA. Genotyping of the selected SNP(rs2241766T>G) in the adiponectin gene was carried out by (PCR-RFLP) technique. Results: After controlling for the age, body mass index, significant difference in Waist circumferences, fasting insulin, HOMA-IR, and serum adiponectin levels were found in PCOS group with respects to those of a healthy control group. Genotyping and alleles results of the selected SNP (rs2241766T>G) were not associated with incident of PCOS. However, women with PCOS with TG and GG genotype had higher insulin levels, and HOMA-IR than carriers of the TT genotype. Conclusions: The current study point out that the selected SNP (rs2241766T>G) in adiponectin gene is not related to PCOS in Iraqi women. Nevertheless, the selected polymorphism was found to be associated with insulin levels, and HOMA-IR among Iraqi women with PCOS, and to impact adiponectin secretion. Further research with a greater sample size, and more SNPs in adiponectin gene are wanting to confirm these results.

Keywords: Polycystic ovary syndrome, genotyping, serum adiponectin, adiponectin gene, SNPs.

1. Introduction

Polycystic ovarian syndrome is one of the most common endocrine/metabolic syndrome of women in their reproductive age(Zhang et al., 2014). Hyperandrogenism is the mark of PCOS linked to disorder menstrual cycles, anovulation and /or oligo-ovulation (Kambalachenu et al., 2013). PCOS is frequently connected with components of metabolic syndrome, such as, insulin resistance, dyslipidemia, obesity, type 2 diabetes mellitus (T2DM) and long –term cardiovascular complications(Moran et al., 2010 and Cupisti et al. 2008).

Adiponectin is a cytokine secreted from white adipose tissue. It has insulin sensitizing properties as well as anti-inflammatory roles (Ghoshal, and Bhattacharyya , 2015). Adiponectin is encoded by a gene located on chromosome 3q27. It has three exons and two introns. The most common variant of exon2 of adiponectin gene is the rs2241766T>G polymorphism. It has been illustrated to be associated with the levels of serum adiponectin, insulin sensitivity, obesity, and T2DM (Han et al. 2011).

Together adiponectin and insulin resistance are essential elements in the development of PCOS. Thus, it is vital to study if the SNPs in the adiponectin gene plays a critical role in the pathogenesis of PCOS (Zhanget al. 2008).

A number of recent studies have examined the associations between SNPs (rs2241766, and rs1501299) of adiponectin gene and PCOS risk. Unfortunately, the results are inconclusive (Panidiset et al., 2004, Xitaet al., 2005, and Zhanget al., 2012).

Accordingly, the current study was directed to verify the possible effect of the SNP (rs2241766T>G) in the adiponectin gene among Iraqi woman with PCOS. Such attempts are essential to better understand the role of adiponectin gene polymorphism in the development of PCOS, and their impact on serum adiponectin levels, and HOMA-IR in Iraqi women with PCOS.

2. Subject and Methods

The case –control design study was performed on 120 Iraqi women [age range 15-38, age mean (SD) 21.9 (5.8)]. The woman had a body mass index greater than 26Kg/m², and who had not taken hormonal therapy for >3 month were recruited in this study. Among them, 60 women with PCOS, while the other 60 were the control group. Who attended the infertility center at Al-Sader Medical City, Najaf, Iraq. A group of woman diagnosed PCOS based on NIH diagnostic criteria, and a group of 60 woman without any history of infertility and clinical signs of hyperandrogenism were included as controls.

For each subject an information on their age, reproductive history, menarche, hirsutism, and blood sample were collected after obtaining written consent. The research contributes undertook basic physical examinations that involved measurement of weight, height, and waist circumferences.

Five milliliters of blood were taken from all patients after 12 hours fasting, put in aliquots into two tubes. The first was analyzed for serum glucose, lipid profile, insulin and adiponectin levels. The second was used for extraction of...
DNA. An enzymatic colorimetric methods were used for determination of serum triglycerides (TG), high-density lipoprotein cholesterol (HDL-C), and total cholesterol (TC). While, Low-density lipoprotein cholesterol (LDL-C) was calculated using Friedewald’s formula (Friedewald et al. 1972). Serum insulin was determined by ELISA Kit (DRG Instruments GmbH, Germany). Adiponectin was quantified using an ELISA kit (RayBiotech, Inc, USA).

3. Genotyping:
Genomic DNA was obtained from peripheral blood specimens by ReliaPrep™ Blood gDNA Miniprep kit (Promega).

Genotyping of rs2241766T>G adiponectin gene polymorphism was carried out by amplification of extracting DNA. Primers were: Forward 5’-GCAGCTCCTAGAAGTAGACTCTGCTG-3’; Reverses: 5’-GGAGGTCCTGTGAATGAGAGGCC-3’ (Li et al. 2012). Polymerase chain reaction was achieved in a total volume (20µl) PCR mixture containing 100ng/µl template DNA, 1 µl (10pmole primer) of each primer, 5 µl Accpower PCR PreMix. The PCR products were analyzed on 2% agarose gel electrophoresis to evaluate the overall amplification efficiency. The amplification product was restricted by Smal enzyme (BioWord, USA) at 25°C for 4 hours. The reaction mixture contained the PCR products (10µl), Smal (0.3µl, 10U/µl), buffer (2µl) and nuclease free water (8µl). The digestion products were resolved on 3% agarose gel electrophoresis, then viewed using gel documentation system.

Figure 1: PCR product of SNP (rs2241766T>G) in the adiponectin gene analyzed by agarose gel electrophoresis.

4. Statistical analysis
Biochemical variables are presented descriptively as mean and standard deviation. Significant variances in continuous variables between two groups were confirmed by the t-test, using SPSS version 20.0 software. Genotyping and allele frequencies were compared by using a χ² test. Odds ratio (OR) and confidence intervals (CI) were also calculated. Multinomial logistic regression of SPSS windows software was used to assess the association of genotypes and allele frequencies with the PCOS group by different inheritance models. HWE was calculated with the use of the online Hardy-Weinberg 2-Allele calculator software – (WWW.had2know.com).

5. Results
The clinical and biochemical data of the enrolled women were stated in Table 1. Significant difference in Waist circumferences, fasting insulin, HOMA-IR, and serum adiponectin levels were found in POCS group with respects to those of a healthy control group.

No: number. BMI: body mass index, WC: Waist circumference, and sAdiponectin: serum Adiponectin.
The genotype pattern of patients with PCOS demonstrated frequencies of 51.67%, 45%, and 3.33% for those of homozygous (TT), heterozygous (TG), and homozygotes (GG) respectively. Healthy control groups exhibited frequencies of 61.67%, 36.67%, and 2.242% for those of homozygous (TT), heterozygous (TG), and homozygotes (GG) respectively. The minor allele frequency of the T and G in PCOS group was indicated to be 0.742% and 0.258%, respectively, and 83.33%, 16.66%, in the control group respectively. Distribution of genotypes and alleles were not differed significantly between PCOS and control participants. Additionally, genotype results of the selected SNP in the adiponectin gene were in Hardy-Weinberg equilibrium (Table 2).

Biochemical characteristics of the patients with PCOS were analyzed with respect to the dominant model (TT vs TG+GG). With regard to the selected SNP (rs2241766T>G), there were no significant differences in a number of women, BMI, age, and fasting blood glucose between different genotypes. Also, lipid profile were similar. Conversely, in PCOS women with the (TG+GG) genotype compared with those with the TT genotype, insulin concentrations, and HOMA-IR were significantly greater.

6. Discussion

Polycystic ovary syndrome is complex multigenic and heteroplasmic disease, and result from the interaction between various susceptibility genes with each other to and environmental factors (Zhang et al., 2014). Therefore, the relationship between single nucleotide polymorphisms and PCOS has become a subject of interest. Most attention has been given to adipocyte secretory proteins (adipokines), particularly focus on adiponectin (Trujillo et al. 2005). Hypoadiponectinemia is closely linked to metabolic syndrome, insulin resistance, and diabetes (Mazloomi et al., 2012, and Kernet et al., 2003). Women with PCOS have an amplified incidence of metabolic syndrome. Insulin resistance with profitable hyperinsulinemia and hypoadiponectinemia free of obesity has been stated in PCOS (Homburg 1996).

When various models of inheritance were considered, unfortunately the difference among the two groups remained insignificant (Table 4). No significant difference was observed in the allele frequency of PCOS patients with respect to those in the control group (OR=1.333, 95%CI: 0.564-3.155, P=0.513).

Table 3: Genotyping and allelic results of rs2241766 T>G in the adiponectin gene of PCOS and control groups in association to different inherited models.

It has been recommended that decline in serum adiponectin levels linked with obesity, the development of insulin resistance, and metabolic syndrome (Zhanget et al. 2008). In the present study, we determined the levels of serum adiponectin in women with PCOS and age and BMI matched healthy women. The plasma adiponectin concentration is lower in women with PCOS and age and BMI matched healthy women. The plasma adiponectin concentration is lower in PCOS group. Accordingly, the data proposed a critical role of adiponectin (Trujillo et al., 2005). Hypoadiponectinemia is closely linked to metabolic syndrome, insulin resistance, and diabetes (Mazloomi et al., 2012, and Kernet et al., 2003). Women with PCOS have an amplified incidence of metabolic syndrome. Insulin resistance with profitable hyperinsulinemia and hypoadiponectinemia free of obesity has been stated in PCOS (Homburg 1996).

Adiponectin can reduce body weight, improve glucose metabolism and lipid profile. In the other side, adiponectin, represents a major link between obesity and reproduction (Ghoshal & Bhatt, 2015). Higher adiponectin levels are connected with enhanced menstrual function and well products in helping reproductive cycles (Allaway et al., 2016).

Numerous single nucleotide polymorphisms (SNPs) located in the adiponectin gene have been related to circulating
vascular disease.

1. The results of the small sample size of PCOS women. Although the difference was not significant, may be as a low adiponectin levels than those with TT genotype, genotype. In addition, PCOS patients with TG and GG had similar distribution of the allelic variant in the PCOS and control group. Furthermore, carriers of the TG and GG genotype were more hyperinsulinemia, and insulin resistance compared with the PCOS women with the TT genotype. In addition, PCOS patients with TG and GG had low adiponectin levels than those with TT genotype, although the difference was not significant, may be as a result of the small sample size of PCOS women.

2. It is essential considered some limitations of the current study. First, the study has a case-control design. It would be limited by links SNPs in candidate genes with disease, and unable to point the disease that may arise on account of population stratification by ethnicity or environmental factors. Second, only one SNPs within the adiponectin gene were evaluated for its relation with PCOS, and not all of the SNPs stated in the literature. Third, the disparity between our results and assumptions may be due to the relatively small number of patient and control women.

3. However, our results highlight that the selected polymorphism in the adiponectin gene have approximately similar distribution of the allelic variant in the PCOS and the control group. Furthermore, carriers of the TG and GG genotype were more hyperinsulinemia, and insulin resistance compared with the PCOS women with the TT genotype. In addition, PCOS patients with TG and GG had low adiponectin levels than those with TT genotype, although the difference was not significant, may be as a result of the small sample size of PCOS women.

7. Conclusion

The current study point out that the selected SNP (rs2241766G>T) in adiponectin gene is not related to PCOS in Iraqi women. Nevertheless, the selected polymorphism was found to be associated with insulin levels, and HOMA-IR among Iraqi women with PCOS, and to impact adiponectin secretion. Further research with a greater sample size, and more SNPs in adiponectin gene polymorphisms are wanting to confirm these results.
