Cryptography Techniques based on Security of AODV in MANETs - A Survey

Ankita Singh¹, Mahima Sharma²
School of Computing Science & Engineering, Galgotias University, Greater Noida, Uttar Pradesh, India

Abstract: Network’s popularity and demand has motivated the development of mobile adhoc networks (MANETs). MANETs are a kind of wireless adhoc network which is infrastructure less. Each device or nodes are free to move independently in any random direction due to this links between the devices is not constant. This dynamic nature of network topology makes security issues more complex. In this paper, we discuss the solutions for security threats in AODV protocol. Security threats like wormhole attack, black hole attack, eavesdropping etc can defended by using cryptographic techniques like RSA, DES, AES. Main issues with security mechanisms that are available is their effect on performance of algorithm like more processing power, packet drop, throughput etc. Finally, concluding over the solutions for security through these algorithms so that performance and security can be enhanced in future.

Keyword: MANET; adhoc; AODV; AES; DES; RSA

1. Introduction

A wireless adhoc network is temporarily set network by wireless mobile computers moving arbitrary in the place that have no fixed infrastructure and all of the transmission links are established through wireless medium. MANETs are a kind of wireless adhoc network. Each node in a MANET is free to move independently in any direction leads to changing its links to other nodes frequently. Due to their self-organizing nature they do not require expensive fixed infrastructures. Evidently, these types of networks are more vulnerable to threats because of dynamic topology. In ad hoc networks, routing protocols are categorized in two groups; the reactive routing protocols and proactive routing protocols. Among the MANET routing protocols, proactive routing protocols have gained more attention; a reactive routing protocol discovers a route only when needed. This enables a reactive routing protocol to achieve better performance than the proactive routing protocols, which discovers and maintains all possible routes in the network even though they may never be used.

AODV routing protocol is an improvement of DSDV, it typically minimizes the number of required broadcast by creating routes if it is required, not as in DSDV in which maintaining a complete list of routes is done. AODV does not specify any special security measures and is vulnerable to many types of attacks that manipulate its routing control mechanism. Among the attacks to AODV routing protocol is the black hole attack, so the black hole node can disrupt network operations and disobey the AODV routing specification. These threats make this protocol less reliable.

2. Routing in MANETS

In MANETs each node works as a router by which overhead of routing get reduced compared to wired networks. Nodes can communicate with each other if they are in communication range of each other; if they are not then the sender sends message through intermediate nodes.

As nature of MANETs is unpredictable and dynamic nodes do not have prior knowledge about topology due to which nodes has identify the efficient topology to start the transmission.

Role of routing protocol is even more challenging in the case of MANETs routing, as it has various constraints with vibrant topology which makes it complex to manage.

The primary goal of any routing protocol is to set up an optimal route which has minimal overhead and consumes minimum bandwidth possible.

MANET routing protocols are categorized in three categories:

- **Proactive**
  Routes are computed prior to requirement. Periodical update and distribution of routing information is performed. Example- DSDV, OLSR, WRP, CGSR, FSR

- **Reactive**
  Routes are discovered when in demand. No requirements of distribution of routing information. Example-AODV, DSR, ACOR, ABR

- **Hybrid**
  A combination of benefits of proactive and reactive protocol is implemented. Example- TORA, ZRP, ARPAM, OORP, HSR, CGSR, LANMAR.
Proactive protocol has advantage of selecting route immediately when required without holding. But it has drawback of higher bandwidth and slow reaction on failures. Reactive protocol consumes less bandwidth and effective in routing. Drawback is it takes higher time for route discovery and sometimes congestion is faced when flooding requests are received. Efficiency of hybrid protocol depends on the number of nodes and the amount of traffic decides the reaction to requests received.

3. Adhoc on Demand Vector protocol (AODV)

AODV is a reactive type of routing protocol in MANETs. Route discovery is not initiated until it is required (on-demand), the protocol operates in two phases: Route Discovery and Route Maintenance. Route discovery is used when a source node want to send message to a target node without the routing, it sends/broadcast RREQ first. When the adjacent node received RREQ with the addresses of source node and target node, before forwarding, it keeps a reverse path to the source node in its routing table. The routing table records the route information of the next hop, the distance and the current highest sequence number it has seen then it judges if it was the same with the target node’s address. If it was, then it sends the RREP to source node, otherwise, checking the routings in the route table that could reach the target node, then it sends RREP to source node, or continue to flooding sent RREQ. Source node receives multiple RREP packets via different paths. Source node selects fresher and shorter path among them to send the application data. AODV protocol maintains routing nodes through broadcasting hello message regularly. If one link breaks, it sends ERROR message to nodes, meanwhile deleting broken records or repairing the routing.

4. Security Goals and Attacks

Information or data in network is an asset which needs to be secured from attacks. Information needs to be protected from unauthorized access (confidentiality), protected from unauthorized change (integrity) and available to legal users when it is demanded (availability). Security goals are as follows:

Confidentiality: privacy of information is kept from false users. When piece of information is send, it has to be conceal while transmission.

Integrity: Integrity means that changes in data need to be done by authorized entities. Information should not be spoiled during transmission.

Availability: The information should be available to authorized users. Assuring the network service is also available to all authorized users.

Attacks in MANETs

- Internal Attacks: Attackers act as one of the nodes among other nodes. Attacker’s gains direct access to the network by impersonation of a proper node and then it perform malicious activities.
- External attacks: Attackers attack from outside the network, it causes congestion in the network by propagating non meaningful message throughout the network, and then it disturbs the whole communication.

Some other types of attacks are:-

a) Impersonation: The attacker can act as a normal node and joins the network and can harm the network. Several this kind of nodes altogether can have control over a whole network and conduct malicious behaviour.

b) Denial of service: Malicious nodes generate false messages in order to disrupt the network’s operation and they consume other node resources.

c) Wormhole attack: This kind of attack is launched by two malicious nodes (worms) connected via a high speed wired or wireless link called wormhole link or tunnel. Then communication of outside nodes is done via this tunnel by multi hop, they encapsulate data packets and falsify the route length.
5. Cryptographic Techniques for security in MANETs

Cryptographic mechanism can be considered as the most reliable technique to guarantee integrity, availability and confidentiality by key management. An original message (plain text) is converted into cipher text by process of encryption at sender side then restoring the plain text from cipher text is done by decryption process at receivers end. Scheme used for encryption constitute the area of study known as cryptography. Cryptographic techniques are categorized into two types.

Cryptographic techniques:

- Private key cryptography:
The same shared secret key is used for both encryption and decryption at sender’s and receiver’s end respectively. It is also known as symmetric key cryptography. Every pair of communicating nodes share a secret key, which means that for n entities to communicate securely, the number of keys required is $K = n*(n-1)/2$.

Some of the algorithms which come under this category are AES, DES, DEA, RC2, BLOWFISH etc.

- Public key cryptography:
Two different keys are required in this technique for each node. A public key is used to encrypt the message at sender’s end and a private key is used to decrypt the message at receiver’s end. It is also called asymmetric key cryptography. This technique requires fewer unit of keys compared to symmetric key cryptography, the number of keys is $K = 2^n$, for n communicating nodes. Some of the algorithms which are included in this category are RSA, Diffie-Hellman key agreement and Digital signature algorithm.

1. Symmetric Key algorithms:
a. Advanced Encryption Standard (AES)
AES technique is not only used for securing but also for high speed. Encrypts data blocks of 128 bits in 10, 12, 14 rounds depending on key size.

AES is fast and flexible. It can be made run on various platforms especially on small devices.
3. Mix Columns: The Mix Columns transformation operates at the column level; it transforms each column of the state to a new column.

4. Add Round Key: Add Round Key precedes one column at a time. Add Round Key adds a round key word with each state column matrix; the operation in Add Round Key is matrix addition. The last step consists of XORing the output of the previous three steps with four words from the key schedule. And the last round for encryption does not involve the “Mix columns” step.

5. Decryption: Decryption involves reversing all the steps taken in encryption using inverse functions like a) Inverse shift rows, b) Inverse substitute bytes, c) Add round key, and d) Inverse mix columns.

b) Data Encryption Standard (DES)

DES (Data Encryption Standard) algorithm purpose is to provide a standard method for protecting sensitive commercial and unclassified data. In this same key used for encryption and decryption process.

DES algorithm consists of the following steps

Encryption
1) DES accepts an input of 64-bit long plaintext and 56-bit key (8 bits of parity) and produce output of 64 bit block.
2) The plaintext block has to shift the bits around.
3) The 8 parity bits are removed from the key by subjecting the key to its Key Permutation.
4) The plaintext and key will processed by following steps:
   i. The key is split into two 28 halves
   ii. Each half of the key is shifted (rotated) by one or two bits, depending on the round.
   iii. The halves are recombined and subject to a compression permutation to reduce the key from 56 bits to 48 bits. This compressed keys used to encrypt this round’s plaintext block.
   iv. The rotated key halves from step 2 are used in next round.
   v. The data block is split into two 32-bit halves.
   vi. One half is subject to an expansion permutation to increase its size to 48 bits.
   vii. Output of step 6 is exclusive-OR’ed with the 48-bits compressed key from step 3.
   viii. Output of step 7 is fed into an S-box, which substitutes key bits and reduces the 48-bit block down to 32-bits.
   ix. Output of step 8 is subject to a P-box to permute the bits.
   x. The output from the P-box is exclusive-OR’ed with other half of the data block. k. The two data halves are swapped and become the next round’s input.

DES algorithms purpose is to provide a standard method for protecting sensitive commercial and unclassified data. DES has small key size of 56 bits. It suffers from the problem of simple relation in keys. It is also susceptible to linear cryptanalysis attacks.

2) Asymmetric key algorithm:

a) Rivest-Shamir Adlemen (RSA)

RSA is widely used Public-Key algorithm. RSA firstly described in 1977. In our proposed work, we are using RSA algorithm to encrypt the data to provide security so that only the concerned user can access it.

RSA algorithm involves these steps:

i. Key Generation
   Before the data is encrypted, Key generation should be done.
   Steps:
   1. Generate two large distinct primes’ p and q
   2. Compute n = p*q and φ(n) = (p − 1)(q − 1)
   3. Select an e, 1 < e < φ(n), relatively prime to φ(n).
   4. Compute the unique integer d, 1 < d < φ(n) where e*d ≡ 1 (mod φ(n)).
   5. Return public key (n, e) and private key d

ii. Encryption: Encryption is the process of converting original plain text (data) into cipher text (data).
   Encryption with key (n, e)
   1. Represent the message as an integer m € {0, ..., n−1}
   2. Compute c = me mod n
iii **Decryption**: Decryption is the process of converting the cipher text (data) to the original plain text (data).

Decryption with key d: compute \( m = cd \mod n \).

The four text files of different sizes are used to conduct four experiments, where a comparison of three.

Algorithms AES, DES and RSA is performed. Performance of encryption algorithm is evaluated considering the following parameters.

A. Encryption Time
B. Decryption Time

The encryption time is the time that an encryption algorithm takes to produce a cipher text from a plain text. Encryption time is used to calculate the throughput of an encryption scheme, is calculated as the total plaintext in bytes encrypted divided by the encryption time. Comparisons analyses of the results of the selected different encryption scheme are performed.

Experimental results for encryption algorithms

AES, DES and RSA are shown in figure 8, which shows the comparison of three algorithms AES, DES and RSA using same text file for four experiments.

Following table has experimented results.

### 6. Conclusion

Encryption technique plays a very crucial role in the world of networking security. Our paper surveyed the existing techniques like AES, DES, RSA algorithms based on their characteristics and performance. It has concluded that AES algorithm consumes least encryption time whereas RSA consumes longest encryption time but it has strong security. We also concluded that Decryption of AES is much better than other experimented algorithms. To get strong technique merits of AES and RSA can be integrated. Speed of AES and security of RSA can result into effective algorithm for encryption in a way to provide security to communication in network.
