Abstract: The performance and quality of components such as power steering, radiator, brakes, steering, clutch, engine, gears and air conditioner is mainly determined by the exact filling with fluids. The fluid pressure, concentration and physical properties are very important from the working point of view. In order to ensure correct working of such fluid filling machines, it is necessary to eliminate their problems causing huge assembly line downtime. The paper describes few suggestions to eliminate the problems occurring in the brake oil and coolant filling machine used for filling the fluids in the cars. The continuous observation and thorough analysis have resulted into the data described here.

Keywords: brake oil, coolant, filling machine

1. Introduction

Brake spongy is the soft feeling of brake pedal that means brake pedal travel before any action takes place in brake system. It should be between 1 to 3 mm, if brake pedal free play is greater than 3 mm it causes brake spongy. Brake spongy is related to forces in braking system, brake system components, brake fluid filling equipment.[²]

This equipment is designed to automatically fill vehicle air conditioning and brake circuits. The circuits are filled using adapter(s). The adapters (or filling heads) are the main tools used by the operator. The system components are as follows:

• A Main Control Panel (MCP) including PLC
• An HMI operating panel
• One Fixed Unit electrical panels, including relays, protection devices, etc.
• Two hydraulic/pneumatic base units one for the Air Conditioning process (AC), one for the Brake process (BK)

One mobile filling unit including the Air Conditioning hydraulic, the Brake hydraulic and the electrical parts, the fill adapters and ABS connector.

The mobile unit is equipped with a tractor drive unit to follow the vehicle movement on the line. The filling cycles are automatic. The operator must be present at the start and end of the cycle.

The AC/Brake filling equipment is divided into (4) major subsystems as follows:

• One Main Control Panel (MCP).
• This panel is connected to the HMI of the equipment that is installed on a separated support.
• One Electrical Fixed Unit Panel
• Two Hydraulic / Pneumatic Base Units (one for AC and one for BK)
• One Mobile Unit for on line fluid dispensing

2. Sequence of Operation

• Pressurization (Only for Coolant Filling): Filling the complete circuit with pressurized air to check any leakage. As the coolant circuit in the car is spread over a wide area and having long pipes, it is necessary to check the leakage in the circuit by filling pressurized air into it.
• Stabilization (Only for Coolant Filling): Waiting till the pressure in the circuit stabilize. Some time is allowed to stabilize the pressure in the circuit
• Pressure test (Only for Coolant Filling): Checking the pressure of air inside the circuit
• Vacuuming (Vacuum 1 and vacuum 2): Removing the air from the circuit with the dirt, dust etc.
• High Pressure Filling: Filling the fluid with high pressure so that it will reach to every part of the circuit
• Low Pressure Filling: Filling the fluid with low pressure so that it will not overflow
• Levelling: Adjusting the final required level of fluid in the tank

3. Observations

Following are some of the faults observed in filling machines

- **Mass under target**: It shows that the mass of the fluid filled in the vehicle tank is less than the required quantity
  
  Possible causes:
  1. Fluid meter malfunctioning
  2. Insufficient fluid in the supply tank
  3. Filling time set is lesser than required

- **Mass over target**: It shows that the mass of the fluid filled in the vehicle tank is more than the required quantity
  
  Possible causes:
  1. Fluid meter malfunctioning
  2. Improper quantity of water and glycol mixed
  3. Filling time set is more than required

</tbody>
</table>

- **Density fault**: This shows that the density value of the water-glycol mixture is out of the required range.
  
  Possible causes:
  1. Improper quantity of water and glycol mixed

</tr>
</tbody>
</table>

- **ABS actuation Fault**: It indicates that the ABS system is not actuated which is required for brake fluid filling in vehicles provided with ABS
  
  Possible causes:
  1. Communication error between electric supply and ABS socket
  2. Ignition key not switched to ON position

5. Conclusion

The faults occurring in the brake and coolant oil filling machine can be easily eliminated by thorough analysis and continuous observation of the process. The elimination of small faults occurring in the coolant and brake oil filling machine can lead to reduction of the vehicle assembly line downtime.
