In-vitro Growth and Inhibition Studies of Tribulus Terrestris on Calcium Oxalate Monohydrate Crystals

R. Selvaraju¹, S. Sulochana²

Department of Engineering Physics, Annamalai University, Annamalai nagar-608002, Tamil nadu, India

Abstract: Problem statement: A many number of people in this world are suffering from urinary stone problem in different age groups. Nephrolithiasis is the term given to a metabolic conditions in which the signs and symptoms results from the deposition of crystals of Calcium Oxalate Monohydrate (COM) in various connective tissues. Approach: It was quite very difficult to grow good quality of large COM crystals because COM was having very low solubility in any known solvents. Results: Attempts were made in the present investigation to grow COM crystals in vitro by single diffusion gel growth technique which is quite suitable to mimic the growth of COM crystals in vivo up to a certain extent. Good quality tiny crystals were grown by gel method which was characterized by FTIR, Powder X-ray diffraction and Thermo gravimetric analysis. The characterization study confirmed the formation of COM crystals in the experiments. Herbal extract solutions of tribulus terrestris were used for the growth inhibition study of calcium oxalate crystals. Aqueous herbal extract solutions were powdered as supernatant solution along with the control solution on the set gels during the growth experiment. Conclusion: Tribulus terrestris extract dissolved COM crystals after 21 days of pouring the supernatant solution on the gel. This in vitro study may be helpful for in vivo studies, which may further lead to develop a preclinical formulation for kidney stone treatment.

Keywords: COM crystals, powder X-ray diffraction, thermal stability, herbal extracts

1. Introduction

The formation of urinary calculi is known as nephrolithiasis. Urinary calculi affected to many people in various age groups in this world. Urinary calculi is one of the most hazardous and painful existing urological disorder causing threat to the global population (1-2). The mechanism of formation of the biological crystals involves the combinations of organic and inorganic chemical compositions. The crystalline deposition is due to trace element in blood vessels, urinary tract, kidney urinary bladder and gallbladder in human beings. Since ancient times and an estimate recurrence rate of 50% (3-4). Hence nephrolithiasis is a significant health problem. Analysis of stone compositions have clearly reported that calcium oxalate is the most frequent crystalline phase in human stones and calcium oxalate is the primary constituent of the majority stones(5). Calcium oxalate has low solubility in water cand crystallizes in 3 hydrated forms Calcium Oxalate Monohydrate (COM), Calcium Oxalate Dihydrate (COD), and Calcium Oxalate Trihydrate (COT). Among these COD and COT are difficult to form urinary stone because they are unstable and easy to eject from body along with urine(6). COM is the most thermodynamically stable form of calcium oxalate and occupies in biggest proportion of all the urinary stones(7-8). Several steps are involved in the formation of the crystals, which are nucleation growth and aggregation. The urinary stone formation begins from the occurrence of nuclei and the formation of these nuclei is from supersaturated urine. The super saturation also depends on urinary PH, ionic strength, solute concentration of certain glycoprotein’s and the pathogenic factors, which are quite complex and are studied (9). Many researchers have attempted to grow COM crystals by gel growth method (10). From this description of accumulated knowledge about the role of calcium oxalate crystals in urinary stone as well as urolithiasis. The slow and controlled diffusion of nutrients to the growing crystals in the gel medium is very useful to study the growth and inhibition conditions, which can be extended to urinary calculi by adding different inhibiting solutions. An important to grow and characterize COM crystals and study the inhibutive effect of various herbal extracts on its growth. The growth and inhibition study provides very useful information regarding the potent herbal extracts or herbal formulations, which can inhibit the growth of crystals in vitro and may be useful in prevention and cure of this crystal induce ailments.

In the present work, the in-vitro growth of calcium oxalate monohydrate crystal by single diffusion gel growth method in silica gel medium. The harvested crystals were studied by FTIR spectroscopy, powder XRD, thermal analysis by TGA/DTA and the effect of aqueous extracts of Tribulus terrestris are studied on the inhibition of growth in the COM crystals.

2. Materials and Methods

2.1 Crystal growth

The single diffusion gel growth method was used to grow calcium oxalate monohydrate crystal. Distilled water and AR grade chemicals were used to grow the crystals.

The glass test tubes of 25mm diameter and 150mm length were used as crystal growth apparatus. Sodium metasilicate (SMS) solution of 1.03 specific gravity was used to prepare the gel. The sodium meta silicate solution was mixed with 5% acetic acid and PH is adjusted to 6. One of the reactant calcium chloride is incorporated inside the gel. After setting the gel, an aqueous solution of oxalic acid was slowly poured over it. Immediately a white column of tiny crystals were
grown, which are shown in Fig 1. The chemical reaction inside the gel can be expressed as:

\[ \text{CaCl}_2\cdot\text{H}_2\text{O} + \text{C}_2\text{O}_4^2\rightarrow \text{CaC}_2\text{O}_4 + 2\text{HCl} \]

The COM crystal as shown in fig.2. The harvested crystals are characterized by FTIR, XRD and TG/DTA techniques.

2.2 Herbal Extract Preparation

The dried and matured seeds of Tribulus terrestris were collected from Botanical garden, Department of Botany, Annamalai University. The collected seeds air-dried fine powder of the fruits of Tribulus terrestris. The aqueous extract of tribulus terrestris is prepared with 12.5 gm of the fine powder of the fruits of tribulus terrestris boiled in 200ml distilled water for 30 minutes and then filtered twice by whatman No.1 filter paper. The extract solution are stored in sterile bottles and kept at -20°C. The aqueous extract of Tribulus terrestris different concentration using the COM crystal.

2.3 Characterization Techniques

Fourier transform infrared spectrum is recorded by KBr pellet technique using Nicolet IS5 model FT-IR spectrometer with the range 400-4000cm\(^{-1}\) to confirm the functional groups and the formation of the crystalline compound. Powder X-ray diffraction of the samples are carried out by EXPERT-PRO diffractometer with CuK\(\alpha\) radiation (\(\lambda = 1.5418\text{Å}\)). The powder XRD data are comparing the JCPDS file. The TGA/DTA spectrum obtained by NETZSCH STA 449F3 heating sample from room temperature to 600°C in an atmosphere of nitrogen with heating rate of standard procedure.

3. Results and Discussion

The single gel method is found to be simple method to grow COM crystals. This method provided to understand the growth of urinary crystal in-vitro.

3.1 Fourier Transform Infrared Spectral Analysis

The FT-IR spectrum of COM crystal as shown in fig.3 and FT-IR assignments of COM crystal are listed in the table 1. The absorption peaks at 3430cm\(^{-1}\) and 3254 cm\(^{-1}\) are due to O-H stretching vibration respectively. 1620cm\(^{-1}\), 1316cm\(^{-1}\) and 1031cm\(^{-1}\) are due to C=O stretching vibrations. 947 cm\(^{-1}\) are due to C=O stretching vibration. 884 cm\(^{-1}\) and 781 cm\(^{-1}\) are due to C-C stretching vibration. 518 cm\(^{-1}\) are due to presence of oxygen-calcium bond.

Figure 4: X-Ray Diffraction Pattern of COM Crystal

3.2 Powder x-ray diffraction of Com Crystal

The powder XRD pattern of COM crystal is shown in fig4 and Table 2 gives the data. The data confirm the presence of Calcium Oxalate Monohydrate in the form of whewellite CaOx vide JCPDS card 77-1160. The results confirm the purity and crystalline nature form. The COM crystal system is monoclinic. The lattice parameters of COM crystal is a=6.24, b=14.58 and c=9.89 respectively. The samples are highly crystalline in nature. The results of the pure crystal are in good agreement with the reported to the value.

3.3 Thermal Analysis of COM Crystal

TGA/DTA curves recorded for COM crystal as shown in fig 5. The loss of water crystallization in first step, carbon monoxide in second step, and carbon-di-oxide in third step. In the first stage weight loss of about 3% occurs between 20°C-140°C which indicates the loss of water hydration. In the second stage weight loss about 15.15% occurred at temperature range between 140°C-240°C corresponding to dehydration of sample in first stage. In the third stage weight loss of 20% was observed between 240°C-510°C. The decomposition of COM with realsing of CO₂.

3.4 Diffusion and inhibition study

Many author have studied the growth of inhibition of COM crystal. In the present investigation, the inhibitive study of COM is carried out by considering change in the mass value of diffusion co-efficient of Ca²⁺ due to the presence of Tribulus terrestris extract solution.

The inhibition of COM crystal growth followed by the extract of Tribulus terrestris

This study is inference to useful to formulate the necessary Tribulus terrestris dosages to recurrence and prevent of urinary calculi formation.

The inhibition of COM crystals increase as the concentration of Tribulus terrestris increases the number of grown crystals and their average size decreases. The Tribulus terrestris growth of COM crystals in-vitro. The dissolution time of grown COM crystal depends on the concentration of Tribulus terrestris added in the supernatant dissolution occurs faster. This also confirms that Tribulus terrestris readily forms complex with calcium and inhibits the growth of crystals.
Calcium oxalate has low solubility in water and crystallizes in 3 hydrated forms COM,COD,and COT. COM is the most thermodynamically stable form of calcium oxalate and occupies the biggest proportion of all the urinary stones(11). Calcium oxalate mainly forms due to the reaction between the calcium ion and the oxalate ion of oxalic acid. Suryawanshi et al. have studied the growth and study of micro-crystalline calcium oxalate monohydrate crystals by agar gel system(12).

FT-IR spectroscopy is an excellent tool to identify various chemical bonds in a compound. Valarmathi et al. have reported the powder IR spectra of tiny crystals of calcium oxalate monohydrate. The FT-IR spectroscopic study have proved the presence of all functional groups and bonds in calcium oxalate crystals (13).

Vijaya et al. have reported the powder XRD patterns and d values, unit cell parameters of calcium oxalate monohydrate were reported. The powder XRD topohaceous deposits in urinary stone also pin points calcium oxalate as the prime accuse. It is very difficult to obtain the single crystal XRD data on the present calcium oxalate monohydrate crystals because they get tube upon exposure of the atmosphere. However, the present powder XRD study suggests that samples are highly and well crystalline nature(14).

Thermo gravimetric analysis is performed to assess the thermal stability of the substances. Earlier E.L. Simons et al. have reported whereas a very small difference in observed and theoretical values was may be due to that, the quality of thermo gravimetric measurement of COM is affected by the three common experimental variables, heating rate, shape of sample container and size of sample(15).

The growth and inhibition study of various bio-material crystals, particularly responsible for ailments related to urinary stones were studied. Joshi et al. reported the effect of herbal extracts on the growth of calcium oxalate monohydrate. Barros et al. have reported the In-vitro studies in which calcium oxalate precipitation was induced by addition of 0.1m sodium oxalate to unfiltered urine samples from wistar rats and normal humans in absence and presence of phyllanthus niruri extract suggested that extract may interfere with early stages of formation(16).

Rathore et.al. have reported the effect of ingestion of 3g and 10g tamarind pulp (Tamarindus indicus) was studied in normal subjects and in stone formers. Tamarind intake at the 10g showed significant beneficial effect in inhibiting spontaneous crystallization in both normal subjects and in stone formers (17).

Vargas reported the phycocyanin known antioxidant is reported to have potential antiurolitiatic activity as it reduces oxalate levels in kidney tissue significantly (18).

From the table 3. One can easily note that 20ml tribulus terrestris COM give comparatively good inhibition than the others. But aqueous extract of tribulus terrestris was found to be an quickly active. These results were found to be encouraging for the in vivo studies and the formulation of the drug. This study may be helpful to design the therapies for the prevention and cure of urinary stone.

4. Conclusion

Calcium Oxalate Monohydrate crystal were grown using gel method FTIR spectrum of COM crystals confirms the presence of a water crystallization O-H, C=O,O-C bands are identified. The powder XRD results confirm the crystalline nature of the sample and identified the monoclinc crystal structure. The stepwise composition of sample confirmed the structure mechanism of COM crystals Tribulus terrestris extract in vitro growth inhibition study of COM crystal carried out at physiological temperature which could be useful for screening potent inhibitor. This could mimic the no growth of high concentration of Tribulus terrestris.
