Abstract: Strontium aluminate nanophosphor SrAl₄O₇ was prepared by sol-gel method. The obtained materials were characterized by SEM, XRD, EDAX and PL. Monoclinic structure was confirmed by X-ray diffraction analysis, particle size was determined by Scherrer formula. The particles were of somewhat round shaped and interlinked with each other, leading to the formation of bigger particle. Also some irregular aggregations were found in the image. Photoluminescence emission were at 395, 520 and 790 nm corresponding to UV, green and IR regions under excitation for 360 nm.

Keywords: XRD, FTIR, SEM, sol–gel method, Photoluminescence

1. Introduction

Alkaline earth metal oxides combined with aluminium oxide are of great interest in material science because of use as long duration photoluminescence and thermoluminescence pigments. They have potential use as refractory oxides in the steel industry and binder materials in the cement industry [1]. Many efforts have been made to discover host materials as well as activators with high performance for phosphor applications. Sol–gel method represents an attractive and easy alternative method to conventional synthesis method, such as ceramic firing [2–4], precipitation [5, 6], or ion exchange on supported oxides [7]. The sol–gel process is an efficient technique for the preparation of phosphors due to the good mixing of starting materials and relatively low reaction temperature resulting in more homogeneous products than those obtained by direct solid state reactions. With sol–gel technique, a low temperature (950°C) has been reported for the successful preparation of M₄O₇ powders [8]. In this work, preparation of SrAl₄O₇:La³⁺ structure, morphology and luminescence were reported. In recent years, rare earth (RE) doped nanomaterials have attracted wide use in various applications as thin film electroluminescent (TFEL) devices, optoelectronic or cathodoluminescent devices. RE-doped insulators are used in telecommunications, lasers and amplifiers, medical analysis and phosphors, etc. Generally rare earth doped aluminates have greater impact on defect centers within the band gap. The emission of light from the ultra violet, visible and Infra red depends on the host material properties[14-18].

2. Experimental

The Sol-gel procedure of synthesizing nanoparticles is thoroughly described as follow: 98wt% of 2M Strontium acetate [(CH₃.CO0)₂Sr.2H₂O] was dissolved in 25 ml of 2-methoxyethanol with vigorous stirring. All starting materials used in the experiments were in analytical grade and of the high purity. Simultaneously, 5 wt. % of 2M Aluminum acetate [C₄H₆AlO₄.4H₂O] was dissolved in 25 ml of 2-methoxyethanol with vigorous stirring and subsequently, it was added to the first solution to reach 50 ml in total. Then it was stirred for 30 min at room temperature for the second time. Ammonia was slowly added to this solution with a constant stirring until a pH of 10.5 was achieved. After the stirring of the solution for 30 min, acetic acid and ethylene glycol in the ratio 1:1 was added to the solution. The sol was heated at 80°C while being mechanically stirred with a magnetic stirrer. As the evaporation proceeded, the sol turned into a viscous gel. The gel was aged for 2h and then dried at 100°C for about 5h. The resulting materials were well grinded and annealed at 950°C for 5h to obtain SrAl₄O₇ nanopowders. The same procedure was repeated with the 10wt% of Aluminum acetate.

3. Results and Discussion

1. Morphological Study

SEM Analysis

Figure1 shows the SEM image of SrAl₄O₇. The micrograph indicates that nearly all the powder particles were composed of same shape nanoparticles. The presence of bigger particles is attributed to the growth of small particles, which is a result of the sol–gel synthesis. Under the reaction time and temperature, some of the tiny particles underwent a self-induced process, aggregate and growth forming bigger particles.
X-Ray Diffraction (XRD)

The structure and phase purity of the SrAlO phosphor were investigated by XRD. The XRD patterns were obtained and are shown in Fig. 2 for SrAlO diffraction patterns were obtained using CuKα radiation (λ=1.54051 Å). Measurements were made from 2θ=10° to 80° with steps of 0.02°. The XRD patterns of the powders revealed that the structure of SrAlO is Monoclinic, which is match with JCPDS data card No. 25-1289. The crystallites are less than approximately 50-90nm in size appreciable broadening in the X-ray diffraction lines. SEM images SrAlO which is un-uniform and may be due to the formation of fractal attribution to sort of self organization. SEM image of SrAlO sintered at 900ºC for 3hrs appears to irregular shape. The peaks resolved by X-ray diffraction analysis are observed at 19.79, 22.05, 25.199, 25.928, 27.26, 28.39, 30.604, 31.866, 33.60, 34.82, 36.206, 36.500, 36.604, 39.284, 40.402, 43.23, 44.54, 45.394, 46.104, 47.727, 49.984, 51.570, 53.57, 55.10, 56.167, 58.13, 58.937, 59.89, 61.5, 62.80, 63.96, 65.146, 72.69 and 73.62 diffraction angle which are assigned to 0 2 0, 1 1 1, 0 2 1, 2 2 1, 4 0 0, 1 3 0, 2 2 1, 0 0 2, 2 0 2, 1 3 1, 5 1 1, 3 3 0, 3 2 2, 2 0 2, 3 3 1, 1 3 2, 2 2 2, 3 3 2, 1 3 2, 4 4 0, 7 0 0, 2 2 3, 11 3, 4 4 2, 1 2 3, 7 0 1, 2 0 2, 2 5 2, 7 2 1, 7 2 0, 2 6 0, 2 6 1, 6 0 4 and 8 4 0. The average particle size of the samples obtained at 5 and 10 wt% are 62 and 90nm respectively. That indicates that the average particle size increases with the increase of the Al concentration.

In order to determine the crystallite size of powder, the Williamson–Hall plot has been used as a useful tool for graphical demonstration of any hkl-dependence of broadening within a particular diffraction pattern. In the Williamson–Hall method, it is assumed that the line broadening βhkl of a Bragg reflection (hkl) originating from the small crystallite size follows the Scherrer equation D=Kλ/βhklCosθhkl.

Plotting the value of βhklCosθhkl as a function of 4sinθhkl, the microstrain ε may be estimated from the slope of the line and the crystallite size from the intersection with the vertical axis. Crystallite size of the particles is measured on average as 51 and 82nm before and after thermal treatment, respectively. The difference between Scherrer and
Williamson–Hall may be due to the effects of internal strain not considered in the Scherrer model.

**EDAX Analysis**

The chemical composition of the SrAl\(_4\)O\(_7\) phosphors can be determined by the energy dispersive X-rays spectroscopy. Fig. 4 shows the energy dispersive spectrum of the SrAl\(_4\)O\(_7\).

![Energy dispersive spectrum of SrAl\(_4\)O\(_7\)](image)

**Photoluminescence Analysis**

The photoluminescence emission spectra of the SrAl\(_4\)O\(_7\) shown in the Figure 5, The PL properties of SrAl\(_4\)O\(_7\) nanopowders were measured at room temperature. In this figure, the PL spectra of SrAl\(_4\)O\(_7\) consisted of three parts:

- One weak peak in the blue region,
- One strong band in bluish green region, and
- Other emission bands in red light region.

SrAl\(_4\)O\(_7\) nanocrystals are found to have increased photoluminescence efficiency.

**Conclusion**

In this paper, by using sol-gel method SrAl\(_4\)O\(_7\) nanoparticles for 5 and 10wt% were synthesized. Materials characterization such as; X-ray diffraction (XRD), photoluminescence (PL) emission spectra, scanning electron microscopy (SEM) were analysed. In the results, we report the SrAl\(_4\)O\(_7\) phosphor generates a strong emission at 395 nm,520nm in green region. The prepared SrAl\(_4\)O\(_7\) nanoparticles are applicable for fluorescent lamp and plasma display applications. The prepared Strontium Aluminate nano powder exhibits monoclinic structure.
