Abstract: A multilevel inverter include an array of power electronic devices that generate output voltage in the form of stepped waveform. In this paper, a seven-level inverter using switched-capacitor units is presented. The switched-capacitor multilevel inverter can produce the desired output voltage levels with reduced number of DC voltage sources and switches. It can also step-up the input supply voltage without using a bulky transformer. The level-shifted multicarrier modulation techniques are used for the modulation purpose. Also two modified level-shifted multicarrier modulation techniques are analyzed and compared with respect to T.H.D for a switched-capacitor seven-level inverter. The simulation of switched-capacitor seven-level inverter using level-shifted multicarrier modulation techniques is done using MATLAB/Simulink software.

1. Introduction

A multilevel inverter is a power conversion device that produces an output voltage in the desired levels by using DC voltage sources at the input. A switched-capacitor multilevel inverter consists of only semiconductor switches, capacitors and diodes. There are no magnetic elements and hence they occupy small volume and are light in weight. This type of multilevel inverters can produce a greater number of voltage levels at the output using switched-capacitor units. The switched-capacitor multilevel inverter can produce the desired sinusoidal voltage waveforms at the output using a fewer switching devices and simple control methods. It can also boost the input supply voltage without using a bulky transformer. Three different types of level-shifted multicarrier modulation techniques are used for the modulation purpose. Also, two new modified level-shifted multicarrier modulation techniques are analyzed and compared with respect to T.H.D for a switched capacitor seven-level inverter.

2. Switched-Capacitor Seven-Level Inverter

A switched-capacitor seven-level inverter is a combination of several switched-capacitor units with a cascaded H-bridge. Figure 1 shows a switched-capacitor seven-level inverter. It consists of one DC source, two capacitors, two diodes and eight semiconductor switches. The switches \( S_{a1} \) and \( S_{a2} \) connect the capacitors \( C_1 \) and \( C_2 \) in parallel with the source whereas the switches \( S_{b1} \) and \( S_{b2} \) connect the capacitors \( C_1 \) and \( C_2 \) in series with the source. The capacitors \( C_1 \) and \( C_2 \) are charged when they are connected in parallel with the source and are discharged when they are connected in series with the source. Thus the switches \( S_a \) and \( S_b \) have complementary operation with each other, which means that, when the switch \( S_a \) is turned ON, the switch \( S_b \) must be OFF and vice versa. The switches \( T_1, T_2, T_3 \) and \( T_4 \) form the H-Bridge unit.

The operation of the switched-capacitor seven-level inverter is illustrated in Table 1. Table 1 shows the switching states of different switches to generate the desired output voltage.

The switches \( T_1 \) and \( T_4 \) are operated to produce a positive voltage, while the switches \( T_2 \) and \( T_3 \) are operated to produce the negative level voltage at the output.
Here 1 indicates the ON state of the switch and 0 indicates the OFF state of the switch. $V_{dc}$ is the input voltage and $V_o$ is the output voltage. A zero voltage is generated at the output by turning off all the switches. Figure 2 shows the operation of the switched-capacitor seven-level inverter.

2.2 Advantages and Applications of Switched-Capacitor Multilevel Inverter

The charging and discharging of capacitors in the switched capacitor unit adds up the input voltage. Thus the switched-capacitor multilevel inverter can step-up the input voltage without any bulky transformer. Moreover, the number of DC voltage sources and switches are reduced. As a result, the size, installation area and cost is also reduced. The switched-capacitor multilevel inverter can be used in PV systems, electric vehicles and DC-AC converter applications.

3. Level-Shifted Multicarrier Modulation Techniques

In level-shifted multicarrier modulation techniques, the modulating signal is a sine wave and the carriers are triangular waves. As the name suggests, there are several carriers which are level-shifted. An $m$-level inverter requires $(m-1)$ triangular carriers. All the triangular carriers have same frequency and amplitude.

**3.1 In-Phase Disposition (IPD) Modulation**

**Figure 3:** In-phase Disposition (IPD) Modulation

In this modulation scheme, all the triangular carriers are in phase. An $m$-level inverter requires $(m-1)$ triangular carriers. Figure 3 shows In-Phase Disposition (IPD) Modulation.

**3.2 Alternative Phase Opposite Disposition (APOD) Modulation**

**Figure 4:** Alternative Phase Opposite Disposition (APOD) Modulation

In this modulation scheme, all the triangular carriers are alternatively in opposite disposition. An $m$-level inverter requires $(m-1)$ triangular carriers. Figure 4 shows Alternative Phase Opposite Disposition (APOD) Modulation.

**3.3 Phase Opposite Disposition (POD) Modulation**

**Figure 5:** Phase Opposite Disposition (POD) Modulation

In this modulation scheme, all the triangular carriers above the zero reference are in phase but in opposition with those below the zero reference. An $m$-level inverter requires $(m-1)$ triangular carriers. Figure 5 shows Phase Opposite Disposition (POD) Modulation.

**3.4 Modified In-Phase Disposition Modulation**

**Figure 6:** Modified In-Phase Disposition Modulation

In this modulation scheme, all the triangular carriers are in phase and the modulating signal is a rectified sine wave. An $m$-level inverter requires $(m-1)/2$ triangular carriers. Figure 6 shows Modified In-Phase Disposition Modulation.

**3.5 Modified Alternative Phase Opposite Disposition Modulation**

**Figure 7:** Modified Alternative Phase Opposite Disposition Modulation

In this modulation scheme, all the triangular carriers are alternatively in opposite disposition and the modulating signal is a rectified sine wave. An $m$-level inverter requires...
A switched-capacitor seven-level inverter requires eight switches. The switches used were MOSFETs. Two 1000 µF capacitors are used as the switching capacitors and a 1 kΩ resistor is used as the load. An input supply of 10V DC is given. The switching pulses for the various switches $S_{a1}$, $S_{a2}$, $S_{b1}$, $S_{b2}$, $T_1$, $T_2$, $T_3$ and $T_4$ were generated using level-shifted multicarrier modulation techniques. The modulating signal is a sine wave of 50 Hz frequency and the triangular carriers are of 10 kHz Frequency. The pulses were generated by comparing the modulating signal and carriers with mathematical and logical operators. The simulation results of various level-shifted multicarrier modulation techniques for a switched-capacitor seven-level inverter is shown in the following subsections.

5. Observations

From the simulation results of a switched-capacitor seven-level inverter using level-shifted multicarrier modulation techniques, a comparison on different modulation techniques can be made with respect to the T.H.D obtained. Table 2 shows the comparison between different level-shifted multicarrier modulation techniques for a switched-capacitor seven-level inverter.

6. Conclusion

The operation of a switched-capacitor seven-level inverter was analyzed and studied. The different types of level-shifted multicarrier modulation techniques were studied and compared. The simulation of switched-capacitor seven-level inverter using level-shifted multicarrier modulation techniques was done using MATLAB/Simulink software. It can be concluded from the simulation results that the Modified In-Phase Disposition modulation technique when used, produce the least T.H.D for a switched-capacitor seven-level inverter.
