Abstract: Big data is concern massive amount, complex, growing data set from multiple autonomous sources. It has to deal with large and complex dataset that can be structured, semi-structured or unstructured and will typically not fit into memory to be processed. MapReduce is a programming model for processing large datasets distributed on a large clusters. A rapid growth of data in recent time, Industries and academia required an intelligent data analysis tool that would be helpful to satisfy the need to analysis a large amount of data. MapReduce framework is basically designed to compute data demanding applications to support effective decision making. Since its introduction, remarkable research efforts have been put to make it more familiar to the users subsequently utilized to support the execution of enormous data intensive applications. This survey paper highlights and investigates various applications using recent MapReduce models.

Keywords: MapReduce; Cloud Computing; Hadoop File System (HDFS); Key Value pairs; Hadoop; Big Data

1. Introduction

In the present days, a huge data handling is a prime concern topic for researchers. Many applications like data mining, Image processing, data analytic etc are required processing of massive amount of data. MapReduce is a programming model and an associated implementation for processing and generating large data sets with a parallel, distributed algorithm on a cluster. The real power of MapReduce is the capability to divide and conquer. Take a large problem and break into smaller, more manageable chunks, operate the chunk independently, and then pull it all together at the end.

MapReduce is a processing paradigm of executing data with partitioning and aggregation of intermediate results. It works to process data in parallel in which splitting of data, distribution, synchronization and fault tolerance are handled automatically by the framework. MapReduce framework is famous for large scale data processing and analysis of voluminous datasets in clusters of machines.

[1]Popularity for the term „Cloud-Computing” has been increasing in recent years. There are many great companies such as Yahoo, Google etc. tried to provide related services to business community, even through public users. In addition to the SQL technique, MapReduce, a programming model that realizes implementing large-scale data processing, has been a hot topic that is widely discussed through many studies. Many real-world tasks such as data processing for search engines can be parallel implemented through a simple interface with two functions called Map and Reduce.

A MapReduce framework can be categorized into mainly two steps such as [10]:

A. Map Phase
Initially split the data into key value pair and fed into mapper which in turn process each key value pair and generate intermediate output.

B. Reduce Phase

Enterprises are aware that Big Data has the potential to impact core business processes, provide competitive advantage, and increase revenues [6]. Thus, organizations are exploring ways to make better use of Big Data by analyzing them to find meaningful insights which would lead to better business decisions and add value to their business. Getting information about popular organizations that hold big data are face book, yahoo, twitter and EBay.
Map/Reduce is a highly scalable programming paradigm capable of processing massive volumes of data by means of parallel execution on a large number of commodity computing nodes. It was recently popularized by Google [7], but today the Map/Reduce paradigm has been implemented in many open source projects, the most prominent being the Apache Hadoop [8]. The popularity of Map/Reduce can be qualified to its high scalability, fault-tolerance, simplicity and independence from the programming language or the data storage system.

3. Mapreduce Model

[2] Map-Reduce was created by one of the biggest search engine companies - Google for application development on data-centers with thousands of computing nodes. Nowadays, it has been used across a wide range of domains within Google, including [3]
- Large-scale machine learning problems
- clustering problems for the Google News and Froogle products
- extracting data to produce reports of popular queries (e.g. Google Zeitgeist and Google Trends)
- extracting properties of web pages for new experiments and products (e.g. extraction of geographical locations from a large corpus of Web Pages for localized search)
- processing of satellite imagery data
- Language model processing for statistical machine Translation
- Large-scale graph computations

The programming model can be summarized as follows [3].

The computation takes a set of input \{key, value\} pairs and produces a set of output \{key, value\} pairs. The use of the Map-Reduce library expresses the computation as two functions: Map and Reduce. First, Map characterizes the set of input pairs and produces a set of intermediate \{key, value\} pairs. Afterwards, the Map-Reduce library groups together all intermediate pairs associated with the same intermediate key, and passes them to the Reduce function. Then Reduce merges these tuples with a same key to form a possibly smaller data set. Typically, the result can be just zero or one output value 245 which is produced per Reduce invocation. The overall processing flow of Map-Reduce is schematized in Figure 1.

5. Online Processing

The Velocity dimension, as one of the Vs used to define Big Data, brings many new challenges to traditional data processing approaches and especially to Map/Reduce. Handling Big Data velocity often requires applications with online processing capabilities, which can be broadly defined
as real-time processing of fast and continuously generated data (also known as data streams).

From the business perspective, the goal is normally to obtain insights from these data streams, and to enable prompt reaction to them. This instantaneous reaction can bring business value and competitive advantage to organizations, and therefore has been generating research and commercial interest. Areas such as financial fraud detection and algorithmic trading have been highly interested in this type of solutions.

The Map/Reduce paradigm is not an appropriate solution for this kind of low-latency processing because:

- MapReduce computations are batch processes that start and finish, while computations over streams are continuous tasks that only finish upon user request.
- The inputs of MapReduce computations are snapshots of data stored on files, and the content of these files do not change during processing. Conversely, data streams are continuously generated and unbounded inputs [15].

In order to provide fault tolerance, most of MapReduce implementations, such as Google’s [7] and Hadoop [8], write the results of the Map phase to local files before sending them to the reducers. In addition, these implementations store the output files in distributed and high-overhead file systems (Google File System [16] or HDFS [8], respectively). This extensive file manipulation adds significant latency to the processing pipelines.

- Not every computation can be efficiently expressed using the MapReduce programming paradigm, and the model does not natively support the composition of jobs.

Despite these limitations, the prevalence and success of MapReduce has motivated many researchers to work on systems that leverage some of its advantages, and at the same time try to overcome its limitations when applied to low latency processing.

One of the first projects in this direction was developed by Condie et al. [17]. In this work, the authors proposed an online MapReduce implementation with the goal of supporting online aggregation and continuous queries. In order to reduce the processing latency, the Map and Reduce phases are pipelined by having the Map tasks sending intermediate results to the Reduce tasks. The authors also introduced the idea of executing reducers on snapshots of the data received from the mappers.

6. Related Work

The most related work associated with the introduction of various MapReduce models and its relation with the database processing [19]. This tutorial provides the insight about how to improve the performance by increasing availability of the system in case of failure, reduced network communication overhead, process scheduling etc. [20]

Authors performed a detailed study about its open source implementation-Hadoop and few factors such as 1) I/O mode, the way of a reader retrieving data from the storage system, 2) data parsing, the scheme of a reader parsing the format of records, and 3) indexing, which is used to speeding up data processing.

[27]Despite being featured such as scalability in clusters, ensuring availability, handling failures Google’s MapReduce has been unusable for certain kind of applications requires iterative computation, execution of high-level language such as SQL and work on an Internet desktop grid. Since the MapReduce introduced, numerous MapReduce frameworks have been developed by several companies including Google’s Map/Reduce [9], Apache’s Hadoop MapReduce [8], AMPLab’s spark [11], SASReduce [12], Disco [13] etc. A lot of research has been done to address the issues highlighted above and some recent Map/Reduce implementation helps to overcome the limitations of the prior framework. While we consider databases, an author described salient features of Map/Reduce implementation and its performance comparison with the parallel database. According to report, Map/Reduce works well in different storage systems and provide a good framework to fault tolerance for large jobs [14].

Google encountered the “Big Data” problem very early, because of the large amount of information they had to process and index. They solved this problem by using commodity hardware, and the architecture to tackle this problem was a shared-nothing architecture, popular because of its scalability. [21] [22]

As Google has demonstrated, a shared-nothing system scales faster, because adding new nodes will not create bottlenecks or slow down the system. This system also increases the availability of the system, since there is no single point of failure. This model is called sharding. A shared-nothing system typically partitions its data among many nodes on different databases (assigning different computers to deal with specific users or queries), or may require every node to maintain its own copy of the application's data, using some kind of coordination protocol. This is often referred to as database sharding.

In 2004, Google released the first paper about their technology, the map-reduce algorithm they used for indexing and processing data, and two years later, the paper about BigTable, their distributed storage system. [23] [24]

7. Tools for Big Data Analytics

R is open source software package to perform statistical analysis on data. R is a programming language and mainly used by data scientist statisticians. R is registered under GNU (General Public License). R has various built-in as well as extended functions such as Data extraction, Data Cleaning, Data Loading, Data Transformation, Statistical Analysis, Predictive Modeling, and Data Visualization.

Apache hadoop is an open source java framework for processing and querying vast amounts of data on large clusters of commodity hardware. Hadoop changes the economics and the dynamics of large-scale computing. It enables scalable, cost-effective, flexible and fault-tolerant
solutions. Apache Hadoop has two main features-HDFS (Hadoop Distributed File System) and MapReduce.

[26] Using R with Hadoop will provide an flexible data analytics platform that will scale depending on the size of the dataset to be analyzed. Experienced programmers can be write MapReduce modules in R and run it using Hadoop’s parallel processing Map/Reduce mechanism to identify patterns in the dataset. Hadoop is a very popular framework that provides such parallel processing capabilities. So, we can use R algorithms or analysis processing over Hadoop clusters to get the work done in Figure 2.

![Figure 2: RHadoop](image)

R is one of the most popular open source statistical analysis packages available on the market today. It is cross-platform, has a very wide community support. R can connect with other data stores, such as MySQL, SQLite, MongoDB and Hadoop for data storage activities. Hadoop consists of a lot of components like Mahout, Pig, Hive, HBase etc

8. Conclusion

The primary focus of this survey paper is to highlight some Map/Reduce implementation worked well to accomplish a specific purpose and compared with previously available frameworks. A remarkable performance improvement over the existing system seems after comparison.

The aim of this paper was giving an overview of the Map Reduce concepts in big data analytics. Map Reduce was developed by Google to handle big data analysis which is unstructured data such as web related data. But, it also can be used for structured data. We have discussed a number of Map Reduce models still researchers can develop a more efficient Map Reduce with improved functionalities.
