Abstract: A single-phase bridgeless Cuk ac/dc power factor correction (PFC) rectifier with positive output voltage is designed. For low output voltage product applications, the rectifier is designed to convert high input voltage to low output voltage. Due to no bridge diodes required and thus decreased input conduction losses, the rectifier efficiency can be improved. The proposed rectifier operates in discontinuous conduction mode, and the current-loop circuit is hence not needed. In addition, only a single switch is used in the rectifier to simplify the control circuit design. A simple translation method to have the positive output voltage in the Cuk converter is presented in the rectifier to reduce the component counts and the cost. The operational principles, steady-state analysis, and design procedure of the rectifier are analysed in detail.

Keywords: DC–DC converter, Power factor correction, zcs turn on of switch, zcs turn off of diode

1. Introduction

The current flows through bridge diodes and the power switch S1 during the switch on-time and through bridge diodes and the output diode DO during the switch off-time. Thus, during each switching cycle, the current flows through three power semiconductor devices. As a result, the significant conduction loss caused by the forward voltage drop across the bridge diodes degrades the converter’s efficiency, particularly at low line input voltage. To reduce the conduction losses, the number of semiconductor devices should be reduced in the current path.

Some methods are introduced to reduce conduction losses in Cuk converter. Bridgeless PFC circuits where the current flows through a minimum number of switching devices compared with the conventional PFC rectifier. Accordingly, the converter conduction losses can be significantly reduced, and higher efficiency can be obtained and cost savings.

The Cuk and SEPIC converters have negative output voltages. Therefore, the extra requirement is an inverse amplifier circuit to translate the negative into the positive voltage. The additional inverse amplifier circuit needed thus increases the cost. Obtain the positive output voltage in cuk converter without the inverting amplifier circuit, we transfer the polarity of all the components.

2. Topology of the Converter

The Cuk converters have negative output voltages. Therefore, the extra requirement is needed. An inverse amplifier circuit to translate the negative into the positive voltage. The additional inverse amplifier circuit needed, thus increases the cost.

Figure 2.1: Bridgeless Cuk PFC Rectifier with Negative Output Voltage

Fig.2.1 shows the initial bridgeless Cuk PFC rectifier, which has a negative output voltage, like the existing Cuk PFC rectifier. As noted, for this circuit, an inverting circuit is needed to transfer the negative to the positive output voltage. The operational principles, steady-state analysis, and design procedure of the rectifier are analysed in detail.

By transferring the polarity of all the components we can obtain the bridgeless Cuk PFC rectifier with positive output voltage.

![Figure 2.4: BridgelessCuk PFC Rectifier With Positive Output Voltage](image)

Thus, the feedback control circuit is simpler, and the cost can be also reduced, as compared with the conventional feedback control circuit shown in Fig. 1.2 although the power switch employed in the circuit is floated with a high-side gate driver needed.

**Steady state analysis assumptions**

Before analyzing the rectifier, the analysis of the circuit supposes that the converter is operating at steady state with the following assumptions.

1) The ON-state resistance $R_{DS}$ and parasitic capacitances of the main switch $S_1$ and the forward voltage drops $V_d$ of the diodes are neglected.
2) The input capacitances are large enough such that, during a switching period $T_s$, their voltages are considered to be constant.
3) The output capacitor $C_o$ is sufficiently large that the output voltage is considered to be constant.
4) The proposed converter is operated in DCM.
5) Due to symmetry of the circuit, it is sufficient to analyze the circuit during the positive half-cycle of the input voltage.

**3. Operation of the Converter**

The converter is operated in discontinuous conduction mode. Operation of the converter can be explained through three modes.

**Mode 1 $[t_0 \rightarrow t_1]$** :

![Figure 3.1: Equivalent circuit in mode I (switch $S_1$ is turned on)](image)

This mode starts when switch $S_1$ is turned on, as shown in Figs. 3.1 and 3.2. Input inductor $L_2$ starts to charge linearly in slope of $\frac{V_{ac}(t)}{L_2}$ and diode $D_p$ is forward biased by the inductor current $I_{L_2}$. The voltage across $L_0$ is equal to $V_{ac}(t)$ thus, $L_0$ increases linearly in slope of $\frac{V_{ac}(t)}{L_0}$. The inductor currents of $L_0$ and $L_2$ during this mode are given by $\frac{dI_L}{dt} = \frac{V_{ac}(t)}{L_2} n=2$.

Accordingly, the peak current through the active switch is $S_1$ given by

$$I_{(S_1)PK} = \frac{V_m}{L_e} \ast D_1 \ast T_s$$

where $V_m$ is the amplitude of the input voltage $V_{ac}(t)$, $D_1$ is the switch duty cycle, and $L_e$ is the parallel combination of inductors $L_1$, $L_2$ and $L_0$. 

**Mode 2 $[t_1 \rightarrow t_2]$ :**

![Figure 3.3: Equivalent circuit in mode II (switch $S_1$ is turned off)](image)

This mode starts when switch $S_1$ is turned off, as shown in Fig. 3.3 and Fig. 3.4. Input inductor $L_1$ starts to discharge linearly in slope of $\frac{V_{ac}(t)}{L_2}$. And diode $D_0$ is forward biased by the inductor current $I_{L_2}$. The voltage across $L_0$ is equal to $V_o$; thus, $I_{L_2}$ decreases linearly in slope of $\frac{V_o}{L_0}$. Note that diode $D_0$ is turned off at zero current.
The inductor currents $i_{L_2}$ and $i_{L_0}$ during this mode are given by

$$\frac{di_{L_2}}{dt} = -\frac{V_{ac}(t)}{L_n}$$

$$\frac{di_{L_0}}{dt} = -\frac{V_0(t)}{L_n}$$

**Mode 3 \([t_2 \rightarrow t_3]\):**

During this interval, only diode $D_P$ conducts to provide a path for $L_2$, as shown in Fig. 3.5. Accordingly, the inductors $L_2$ and $L_0$ in this interval behave as constant current source. Thus, the voltage of inductors $L_2$ and $L_0$ is zero. Capacitor $C_2$ is being charged by the inductor current $i_{L_2}$ and the energy of capacitor $C_0$ is released to load. This is a freewheeling mode. The theoretical waveforms in this mode are shown in Fig. 3.6. This mode lasts until the start of a new switching period. The turn off time of the switch and the output diode is given by

$$T_{off} = T_S - t_{on} - t_{don}$$

where $t_{on}$ is the conducting interval of switch $S_1$, and $t_{don}$ is that of the output diode $D_0$. The normalized length of mode II period can be obtained as follows:

$$D_2 = \frac{D_1}{M} \sin \omega t$$

where $\omega$ is the line angular frequency, and $M$ is the voltage conversion ratio ($M = \frac{V_0}{V_{in}}$).

6. Conclusion

The Cuk PFC rectifier with positive output voltage has been analyzed. The simulation results have shown good agreements with the predicted waveforms analyzed in the converter. The PF of the circuit has unity above at all the specified input and output conditions. Moreover, with higher efficiency and high PF, the Cuk PFC rectifier with positive output voltage is able to be applied to most of the consumer electronic products of 150-W rating in the market. In addition, with only a single switch employed, the implemented system control circuit is simple to achieve high PF by applying any pulse width modulation control integrated circuit.
