Abstract: **Objective:** To study the preliminary characteristics and pharmacognostic of *Sorghum bicolor* (L.) cereal used as food in some parts of West Africa. **Methods:** The pharmacognostic study involved performing macroscopic and microscopic examination of fresh and dry medicinal plant. The study of physicochemical parameters consisted of the determination of moisture content, total ash and insoluble sulfur in hydrochloric acid. **Results:** The pharmacognostic examination of this plant has revealed morphological examination revealed an annual grass crop height can reach up to 1 m to 5 m high. The cylindrical and solid stem, which is usually erect, carries a terminal inflorescence in a compact panicle. It includes spikelets of one or two bisexual flowers. The micrograph showed many large translucent tissue structures. These are the endocarp, the aleurone layer and the integuments. **Conclusion:** pharmacognostic analysis and physico-chemical characteristics can help the pharmacopoeia for the efficient utilization of this plant.

Keywords: Pharmacognosy, nutraceuticals, *Sorghum bicolor* (L.)

1. Introduction

Medicinal plants are of great importance to human health. This is why the World Health Organization estimates that 80% of the population in developing countries relies on traditional medicine for their primary health care [1]. Therefore, medicinal plants play important role in the socio-cultural and therapeutic needs of peoples. Some of these plants are used as spices and foods [2; 3], also serve as a resource for research and development of new drugs [4]. In Africa and elsewhere, several ethnobotanical surveys conducted, showed that *Sorghum bicolor* (L.) is a medicinal plant well known and widely used in the treatment of various infections.

*Sorghum bicolor* is a *Poaceae* grown in Africa. It is in the north-east of Africa that we find the greatest diversity of species of the genus *Sorghum* among both cultivated and wild types. *Sorghum* bicolor formerly known *Sorghum vulgare* includes wild weeds and annual cultivated types that are completely infertile (5). It is a plant that is characterized by a strong root system, which largely explains its ability to withstand drought. This species is grown either for its grain, fodder or for its stems (6). However, there is another type of sorghum, the sorghum dye which is extracted from a bio-dye mainly leaf sheaths (7). *Sorghum* bicolor (L.) *Moench.* is a very important crop in the tropical region. The seeds make up the composition for treatment of gonorrhea and cough in Senegal. The decoction of the bark associated with *Pterocarpus erinaceus* (Fabaceae) is used in the treatment against anemia. The decoction of stems, mixed with lemon, is used in the treatment of jaundice in Togo and Niger. The red pigment, which have antimicrobial and antifungal properties, also serves as a remedy for anemia in traditional medicine.. In Ethiopia, the seeds of *Sorghum* bicolor (L.) *Moench.* are used for the treatment of diarrhea (8). Although *Sorghum* bicolor is known for its nutritional value, it is also used for some medicinal properties. Thus, sorghum dye is used in infusion to treat anemia and certain menstrual disorders (7).

2. Materials and Methods

2.1 Plant Material

The plant material consisted of dried fruit of *Sorghum bicolor* (L.) *Moench.* They were purchased from the market in Abidjan. A herbarium of drug was formed and deposited at the National Floristic Center of the Félix Houphouët-Boigny University Abidjan.

2.2 Methods

The drugs were cleaned and dried away from sunlight under laboratory temperature (24 °C-26 °C). The drugs were roughly pulverized using a grinder Retsch SM 2000. Powdered drug was used for the pharmacognostic study and physico-chemical screening.

2.3 Macroscopic Studies

The macroscopic study is a morphological study. This study allowed us to make a description of the plant and determine the shape, texture and color of the drug.

2.4 Organoleptic characteristics study

The study of the organoleptic characteristics covered the powdered drug and concerned the taste, appearance, color and odor of drugs. The smell test was carried out with 1mg of powdered drug taken between thumb and forefinger. The...
Sorghum bicolor (L.) Moench

2.5.2.1 Total ash

The determination of the water content was performed by the gravimetric method according to the protocol created by Linden and Lorient [9] and Mukherjee [10]: 5 tests were performed taking 5 g of powder introduced into 5 calibrated crucibles. The 5 samples were dried in an oven at 105 °C for 24 hours. The crucibles were cooled in a desiccator and weighed. The weights obtained were used to calculate the mass loss and calculate the water content of the powder as a percentage.

2.5.2 Determination of ash content

2.5.2.1 Total ash: The dried powder used for the determination of the moisture content was reduced to ashes in a furnace at 600 °C for 6 hours. After cooling in a desiccator, the ashes were weighed. The weights obtained were used to calculate the masses of ash and calculate the total ash content, expressed as a percentage.

2.5.2.2 Determination of acid insoluble ash value in 10\% hydrochloric acid:

Total ash obtained was mixed with 20 ml of 10\% hydrochloric acid. The whole mixture was boiled in a water bath for 15 minutes. The solution obtained was filtered through Whatman paper. The residue was collected in a crucible and calcined in an oven at 600 °C for 6 hours. The crucible was cooled in a desiccator. The mass of insoluble ash in hydrochloric acid was expressed as a percentage.

2.5.2.3 50\% Sulfuric ashes: Five tests were performed taking 5 g of powder, introduced into crucibles. It was added to the contents of each crucible 5 ml of 50\% H\textsubscript{2}SO\textsubscript{4}. The solution was placed in an oven at the temperature of 600 °C for 6 hours. After calcinations and cooling in a desiccator, the ash was weighed and the mass of sulfuric ash was expressed as a percentage.

3. Results

3.1 Macroscopic Study

This study allowed us to identify the plant material, and is the first step in the characterization of the crude drug.

Morphological characteristics

It is an annual grass crop growing up to 1 m to 5 m high. The stem (culm) cylindrical and compact, usually in erected position carries a terminal inflorescence compact panicle. This includes one or two spikelets bisexual flowers. The leaves are simple and alternate. The leaf blade flat or wavy edges, is lanceolate or linear-lanceolate. It stands erected in the beginning and later folds. 60 cm long inflorescences are terminal panicle.

Sorghum bicolor (L.) Moench. has two types of flower. The lower flower is made solely of a lemma, and the upper flower bisexual, consists of a lemma slit at the apex. The fruits are caryopses (grain), usually partially covered by glumes, 4-8 mm in diameter, rounded and blunt point.

Phytogeography

Sorghum bicolor (L.) Moench. is a species found in the tropical, subtropical and warm temperate regions. This species naturally occupies a vast area extending from the northeast tropical Africa to the whole of Africa and the Middle East to India. This plant is exotic in China, Southeast Asia, in the Americas, Australia, Europe, Argentina and Russia.

3.2 Ecology

Sorghum bicolor (L.) Moench. is a perennial plant and can be harvested several times a year. However, it is treated as an annual. This species has many cultivars, highly polymorphic and grown in the tropics and subtropics. It is grown along coastal waterways. Sorghum bicolor (L.) Moench. develops a long and deeper roots therefore tolerate drought. It can be found on any type of soil and is not found in the wild nature.

4. Discussion

Our study, has focused on examining pharmacognostic study of Sorghum bicolor fruits (L.). The scientific literature has allowed us to review a large number of bibliographic data on this drug, including the systematic and various domestic uses in traditional medicine. The performance of macroscopic and microscopic studies of Sorghum bicolor (L.) remains essential to identify the authenticity of this drug and in other to prevent falsification.

The organoleptic characteristics are very important in drugs because they play a role in distinguishing adulterated or substituted drug from the authentic drug [11]. The Sorghum bicolor (L.) Moench drug, when crushed is powdery in appearance, pink color, has no odor. It has a neutral taste.

The micrograph performed on the drug powder allowed to highlight a number of characteristics elements including: Sclerosing cell pericarp, Endocarp; Aleuorone layer; Tegument; Young sclerosing cell pericarp has many large translucent tissue structures. These are the endocarp, the aleuorone layer and the integuments (12).

The study of physicochemical parameters such as moisture content and ash values are useful to determine the physiological and non-physiological state of ash, to detect the possibility of microbial growth or contamination and finally the presence of impurities. In this study, the drug of S. bicolor (L.) Moench. is constituted by the non-dehulled fruit NDF (and its by-products). Its moisture content was 12.95%.

The study of sorghum fruit revealed that the hulled fruit has a slightly lower moisture content (12.19%) than the non-dehulled fruit. These values are greater than 10% and also those found by BALOLE et al. (2006). These high moisture content, however, remain below the standard indicated by the Codex Alimentarius (15%) (14). This high contents could be due to the hygrometric degree and the drying temperature on one hand and on the other hand, the high moisture content in the unhulled fruit may be due to the presence of abundant mucilage used to store water. The water content, which is less than or equal to the standards, gives the pulverized drugs a better long-term conservation property.

The measurement of total ash gave us a rate of 1.34 ± 0.02. This value, indicated the level of minerals in the drug (15). The sulfuric ash value was 1.79 ± 0.03. They result from the conversion of organic salts to sulfates (15). The ash insoluble in hydrochloric acid gave a rate of 1.98 ± 0.07. Indeed, insoluble ash in hydrochloric acid tells us about the contamination of the drug by siliceous elements (15).

5. Conclusion

This study allowed us to detect the presence of different pharmacognostic parameters in Sorghum bicolor (L.) drug according to botanical standard and WHO guidelines. The value of moisture content found is satisfactory as the moisture content level in the drug studied allows good conservation and prevents oxidative reactions, fermentation and microbial growth.

In light of these results, pharmacognostic analysis and physiochemical characteristics can help in the efficient utilization of this plant as part of a standardization policy, identification and research on Sorghum bicolor (L.) drugs.

6. Acknowledgement

We would like to extend our profound gratitude to the entire staff of Laboratory of Pharmacognosy Faculty of Pharmaceutical and Biological Sciences of the Felix Houphouet Boigny University for their technical support during the performance of this work.
