Effect of Maternal Anemia on Placental and Fetal Outcome

Dr. Sowmya Sri. K¹, Dr. Pramod Kumar Korani Ratnam²

¹Resident, Department of Obstetrics and Gynaecology, Osmania Medical College, Hyderabad
²Assistant Professor, Department of General Medicine, Deccan College of Medical Sciences

Abstract: Anemia during pregnancy is very common. More than one-quarter of the world’s population is anemic. Growth of the fetus is intricately linked with that of placenta, because placenta helps in transfer of nutrients and oxygen from mother to fetus. Placenta is a focus of increasing interest because significant pathology afflicts the placenta, often before affecting the fetus.

Keywords: Anemia, placenta, fetus

1. Introduction

Anemia during pregnancy is very common. More than one-quarter of the world’s population is anemic. Approximately one-half of this burden is a result of iron deficiency anemia, being most prevalent among preschool children and women. More than 70% of pregnant women in developing countries suffer from anemia (1). Functional iron deficiency is a state in which there is insufficient availability of iron (ie, low plasma iron levels and/or low percent transferrin saturation) for incorporation into erythroid precursors in the face of normal or increased body iron stores (ie, normal to increased bone marrow iron stores and/or normal to increased serum ferritin levels) (2,3).

Total iron content of the body depends on age, sex and body weight of the person. In an average adult female it is 2-2.5gms (4). Placental abnormalities can be an ‘early warning system’ for fetal problems. The evaluation of placenta thus becomes essential in high risk pregnancy (5). Maternal anemia leading to low birth weight and perinatal mortality (6). Naoko kozuki (7) et al conducted a meta-analysis study and found that moderate to severe anemia appears to have an association with SGA outcomes. Iron deficiency anemia contributes to more than 90% cases of anemia complicating pregnancy being responsible for 19% of maternal deaths (8).

2. Patients and Methods

Prospective cross sectional study of pregnant cases admitted in the Department of Obstetrics and Gynecology, Osmania medical college over a period of 24months which includes 40 randomly selected subjects, belonging to Control, mild, moderate and severe anemia groups. Anemia due to causes other than IDA, with associated medical disorders and obstetrical complications like preeclampsia, multiple gestation, antepartum hemorrhage were excluded.

3. Observations

In the present study, multigravidae represent 72.5% of the total study Population.

In the control group, multigravidae represent 70% of the controls while in the anemic study population they represent 75.8% of the anemic group

Age Wise Distribution of Study Population:
In the present study, 47.5% belong to 23-27 years age group. 50% of the control population belongs to 23-27 yrs age group and the rest 50% to 18-22yrs age group. In the anemic group, 46.6% belong to 23-27yrs age group, 36.6% belong to 18-22yrs age group and the rest 16.8% to 28-32yrs age group.

Birth Weight Categorization

<table>
<thead>
<tr>
<th>Birth Weight (kg)</th>
<th>Control</th>
<th>Mild</th>
<th>Moderate</th>
<th>Severe</th>
<th>Total</th>

</table>

In the present study, 50% newborns were in the birth weight range of 2.1-2.5kgs. In the control group, 50% of the newborns were in the range of 2.6-3kg. In the anemic group, 60% of the newborns were in the birthweight range of 2.1-2.5kg and 26.6% were in the range of 2.6-3kg and 10% were >3kg

Mode of Delivery in the Study Population
In the control population 60% population had LSCS as the mode of delivery. In the study population, 60% delivered vaginally while 40% underwent LSCS

Distribution of Cord Blood Hemoglobin

</tr>
</tbody>
</table>

In the present study, 12.5% newborns had cord blood hemoglobin less than 13.7gm/dl, considering a level of 13.7-20.1gm/dl(9) to be the normal range. In the present study, cord blood hemoglobin of all the newborns in the control group were in the normal range of 13.7-20.1gm/dl. While 16.6% of the newborns in the anemic group had cord blood hemoglobin less than 13.7gm/dl, rest of the 83.4% had hemoglobin in the normal range
In the present study, 57.5% of the population show increased vascularity. In the present study, 30% of the control population shows increased vascularity, while 66.6% of the anemic group shows increased vascularity.

This is comparable to a study conducted by Amalia Levy et al(10).

**Maternal Serum Ferritin Vs Birth Weight**

In the present study, there was no significant association between maternal serum ferritin concentration and birth weight of newborn among control, mild and moderate anemic mothers.

On the contrary there was significant association between maternal serum ferritin concentration and birth weight of newborn when the maternal hemoglobin falls below 7gm/dl.

**Maternal Hemoglobin Vs Cord Blood Hemoglobin**

In the present study, the correlation coefficient between maternal hemoglobin and cord blood hemoglobin in control, mild and moderate anemia cases there was no significant association between maternal hemoglobin concentration and cord blood hemoglobin.

While in the severe anemia cases there is a significant positive association maternal and cord blood hemoglobin concentrations.

Compared to study AarthiSareen(11).

**Maternal Hemoglobin Vs Cord Blood Ferritin**

In the present study, the correlation coefficient between maternal hemoglobin concentration and cord blood serum ferritin among control, mild and moderate anemia subjects there was no significant association between maternal hemoglobin concentration and cord blood serum ferritin concentration.

On the contrary the correlation coefficient between maternal hemoglobin concentration and cord blood serum ferritin in severe anemia cases here exists a significant positive correlation between maternal hemoglobin concentration and cord blood serum ferritin concentration in the newborn as maternal anemia worsens.

**Maternal Ferritin Vs Cord Blood Ferritin**

In the present study, the correlation coefficient between maternal and cord blood serum ferritin concentration was 0.77387 which implied that there positive correlation exists a significant positive correlation between maternal and cord blood serum ferritin concentrations. This is comparable to study conducted by Erdem.A et al(12).

**Maternal Hemoglobin Vs Length of New Born**

In the present study, the correlation coefficient between maternal hemoglobin and Length of the newborn among control, mild, moderate and severe anemia subjects exists no significant association between maternal hemoglobin concentration in control, mild and moderate anemia groups, while a significant positive correlation exists between maternal hemoglobin and length of the newborn in severe anemia group.

4. Discussion

In this present study a total 40 subjects were studied 10 each belonging to control, mild moderate and severe anemia groups. Hemoglobin, serum ferritin estimation, peripheral smear examination and MCV, MCH was determined for each of the cases. At the time of delivery, birth weight and length of the newborn were determined. Cord blood was collected at the time of delivery for hemoglobin and serum ferritin estimation.

In the present study, taking a birth weight of 2.5kg as cutoff, control and anemic population were grouped into those whose newborns were more than or equal to 2.5kg and those whose newborns were below that.

According to this distribution Birthweight <2.5kg control are 1, anemic are 15 and Birthweight ≥2.5kg control are 9, anemic are 15 there shows there exists a significant association between maternal anemia and low birth weight.
Association between low birth weight and villous vascularity on placental HPE. In this distribution of among birthweight < 2.5kg 6 of them have normal villous vascularity, 10 of them have increased villous vascularity and among birthweight ≥ 2.5kg 11 of them have normal villous vascularity, 13 of them have increased villous vascularity. From this distribution there exists no significant association between birth weight and villous vascularity on placental HPE among the study population.

Association between anemic group and villous vascularity on placental HPE. In this distribution among controls 7 of them have normal villous vascularity, 3 of them have increased villous vascularity and among anemic 10 of them have normal villous vascularity, 20 of them have increased villous vascularity. From this distribution that there exists no significant association between maternal anemia and increased villous vascularity on placental HPE.

Association between birth weight and syncitial knots on placental HPE. In this distribution of among birthweight < 2.5kg 3 of them have normal syncitial knots, 13 of them have increased syncitial knots and among birthweight ≥ 2.5kg 13 of them have normal syncitial knots, 11 of them have increased syncitial knots. From this distribution there exists a significant association between birth weight of newborn and increased syncitial knots on placental HPE.

Association between anemic group and syncitial knots on placental HPE. In this distribution of among control 7 of them have normal syncitial knots, 3 of them have increased syncitial knots and among anemic 10 of them have normal syncitial knots, 20 of them have increased syncitial knots. From this distribution there exists a significant association between anemia and increased syncitial knots on placental HPE.

Association between birthweight and intervillous fibrinoid necrosis placental HPE. In this distribution of among birthweight < 2.5kg 4 of them have normal intervillous fibrinoid necrosis, 12 of them have increased intervillous fibrinoid necrosis and among birthweight ≥ 2.5kg 16 of them have normal intervillous fibrinoid necrosis, 8 of them have increased intervillous fibrinoid necrosis. From this distribution there was a significant association between low birth weight and increased intervillous stromal fibrosis.

Association between anemic and intervillous stromal fibrosis on placental HPE. In this distribution among controls 8 of them have normal intervillous stromal fibrosis, 2 of them have increased intervillous stromal fibrosis and among anemic 12 of them have normal intervillous stromal fibrosis, 18 of them have increased intervillous stromal fibrosis. From this distribution there exists a significant association between maternal anemia and increased intervillous stromal fibrosis on placental HPE.

5. Conclusions

Mild and moderate maternal anemia does not affect birth weight, length, newborn hemoglobin levels, cord blood ferritin and length of the newborn. Severe maternal anemia has a great impact on birth weight, newborn hemoglobin and ferritin levels. Hence inference from present study is to detect maternal anemia at the earliest in a less severe form so that deleterious effects on the foetus in severe anemia can be prevented.
