Review of the Level of Awareness’ Towards Occupational Hazards among Orthodontic Staff at Selected Dental Clinics, Saudi Arabia

Naif Mayouf Alrasheedi
General Dentists, PHC Buraydah, Saudi Arabia

Abstract: Background: Notwithstanding the highlighting on patient safety in dental clinics, Number of hours a dentists works directly affects his health, especially the strained posture the dentist is in despite the fact that treating a patient, which causes anxiety on the spine and limbs and is a major cause for musculoskeletal problems that dentists face. Based on evidence, Majority of the dentists had stress while working on patients. Various clinical procedures such as unanticipated emergency situations, anesthetization of patients, if the patient is not satisfied with the treatment, and unskillful treatment planning contribute to development of situations, which lead to high blood pressure, fatigue, tiredness, and increased stress. Objective: To assess the level of awareness’ towards occupational hazards among orthodontist staff at the selected dental clinics, Saudi Arabia. Method: A cross-sectional survey was conducted at five dental clinics, Saudi Arabia. Forty Two items of self-administered questionnaire was provided to 250 orthodontic staff in the research setting based on their area of their specialties to assess the level of awareness’ towards occupational hazards among orthodontist staff at the selected dental clinics, Saudi Arabia. Results: This study finding showed that awareness towards Occupational Hazards among some orthodontist staff at dental clinics was variable. The majority (87.6%) of the orthodontic staff had a high level of awareness towards Occupational Hazards in relation to Hazards due to Nitrous Oxide Gas. Furthermore, orthodontist staff had a high level of awareness towards Occupational Hazards in relation to Infection (85.6%). On the other hand (66.4%) of the orthodontic staff had a lowest level of awareness towards Occupational Hazards in relation to Stress. Although, concerning the Intermittent Level of Awareness the highest level was awareness towards Occupational Hazards in Occupational in the item Nervousness and anxiety after Work (79.2%). Conclusions: The current study results revealed that there were high levels of awareness among the orthodontic staff towards occupational hazards within the study setting.

Keywords: Occupational Hazards; Awareness review &Orthodontic staff

1. Introduction

Review of literature documented that, The main clinical applications of lasers in dentistry which include Soft tissue, periodontal surgery, Root canal treatment, Desensitization Analgesia, Endodontic, Tooth bleaching and Tooth cavity preparation. The main occupational hazards associated with the use of lasers as Eye damage, Skin damage, Fire and Smoke inhalation (cellular and viral debris). (Pournaras, 2004).

According to Ayatollahi, (2012), 83% of dentists believe dentistry is “very stressful”, with nearly 60% believing that dentistry is more stressful than other professions. Some of the main sources of stress in dentistry include Overcoming pain, Fear, Administration of anesthesia, Patient dissatisfaction with treatment, Running behind schedule, Work–life balance & “Techno-stress”

Professional risk factors in dentistry may harm dentists and their team. Despite numerous technical advances in recent years, many occupational health problems still persist in modern dentistry. These include exposure to infectious diseases, radiation, dental materials, and noise; musculoskeletal disorders; dermatitis and respiratory disorders; eye injuries; and psychological problems. It is essential for an orthodontist to recognize these risk factors and protect against them. The scientific and clinical literature on occupational hazards in orthodontics is reviewed to identify and recognize the risks, new guidelines, precautions and protocols are rapidly instituted to greatly reduce or even eliminate the occupational hazard. (Rapiti, et al., 2005)

Gambhir, R. S. (2011), mentioned that, hazards caused by non adherence to universal precautions by the health care providers, statistics reported by the Central Register of Occupational Diseases in Poland indicates that among 314 new cases of occupational diseases in HCWs in 2005, HBV and HCV represented 42.6% of all cases.9 Despite the substantial reduction in HBV infection since vaccination was introduced in 1989, the incidence of HCV hepatitis in Poland is still on the increase in this occupational group.

Dental care professionals are at risk for occupational exposure to a variety of hazardous chemicals and situations. Being unaware of the potential hazards in the work environment makes them more vulnerable to hazards. Furthermore, Orthodontic staff should have a high level of awareness about occupational hazards enhance consciousness education has not been prominent among dentists. To the maximum of understanding, the special treatment of orthodontic staff in relation to knowledge and awareness about policies of safety measures within the work setting. Consequently, conducted this study to assess the level of awareness’ towards occupational hazards among orthodontic staff at the dental clinics, Saudi Arabia.

Participants and Methods

This study was conducted with orthodontic staff at the selected dental clinics, Saudi Arabia. The study was granted ethical approval by the clinics ethical committee.

The participants were selected from the selected dental clinics. After signing an informed written consent form, the questionnaire was given to each participant. Before administration of the questionnaire, the purpose of the study was explained to each respondent and confidentiality of the information guaranteed.

The research was carried out by one of the authors who were appropriately trained in administering the informed consent and the self-report questionnaire to the participants. In this cross-sectional study, a structured questionnaire prepared by the authors, was administered to the participants. Forty Two-item self-administered structured questionnaire about awareness’ towards occupational hazards among the selected orthodontic staff, who advised de novo and tested.

It included a full range of response options, designed to identify the practitioner’s level of to assess their level awareness’ towards occupational hazards among orthodontic staff within the selected setting. Prior to distribution of the questionnaire, a pilot study was done on a selective group of health care workers who were asked to fill out the questionnaire and return it back with their remarks and criticism. Minor changes were then made to the final tool.

The questionnaire consisted of demographic information such as occupation, age, gender, and the marital status. The second part of the questionnaire comprised of questions regarding their level of awareness’ towards occupational hazards among medical staff. This part also assessed awareness’ towards occupational hazards. It took approximately 30 minutes to complete each appraisal.

The level of awareness’ towards occupational hazards among orthodontic staff among orthodontic staff at the dental clinics, Saudi Arabia. By examining questions. A score of “1” was assigned for a correct answer and “0” for an incorrect answer. A health care worker who obtained a total score of “5” was considered “very aware;” “4 or 3” “somewhat aware;” and “1 or 0” “not aware.” The data were coded and analyzed by SPSS® for Windows® ver. 12.0. Strict confidentiality was maintained. All the data were stored in computers at a secured location, with access provided only to the researchers involved in the study. The \( \chi^2 \) test was used to test association between categorical variables. A p value <0.05 (two-tailed) was considered statistically significant differences.

### Results

This study finding showed that awareness towards Occupational Hazards among some orthodontic staff at dental clinics was variable. The majority (87.6%) of the orthodontic staff had a high level of awareness towards Occupational Hazards in relation to Hazards due to Nitrous Oxide Gas. Furthermore, orthodontic staff had a high level of awareness towards Occupational Hazards in relation to Infection (85.6%). On the other hand (66.4%) of the orthodontic staff had a lowest level of awareness towards Occupational Hazards in relation to Stress. Although, concerning the Intermittent Level of Awareness the highest level was awareness towards Occupational Hazards in Occupational in the item Nervousness and anxiety after Work (79.2%).

### 2. Discussion

This study finding showed that awareness towards Occupational Hazards among some orthodontic staff at dental clinics was variable. The majority (87.6%) of the orthodontic staff had a high level of awareness towards Occupational Hazards in relation to Hazards due to Nitrous Oxide Gas. Furthermore, orthodontic staff had a high level of awareness towards Occupational Hazards in relation to Infection (85.6%). On the other hand (66.4%) of the orthodontic staff had a lowest level of awareness towards Occupational Hazards in relation to Stress. Although, concerning the Intermittent Level of Awareness the highest level was awareness towards Occupational Hazards in Occupational in the item Nervousness and anxiety after Work (79.2%).

It was surprising the majority of the staff who handled mercury were unaware they could be exposed to chronic mercurial poisoning. All dental personnel should be alerted of the risk of mercurial poisoning and should be familiar with the preventive measures provided by the FDI against mercurial poisoning. It is advisable to conduct regular mercury vapor level assessments in clinical settings; receive episodic individual amalgam blood level tests; and use...
goggles, water spray, and suction during the removal of old amalgam restorations.

This study has shown the majority of the staff were aware of the risk of injuries from sharps and needles which is rated to have high occurrence among health workers at least in the United States. In this study, health care workers employed in the health sector for longer periods were more aware of universal precautions compared with those who served for shorter periods. Training and education have been found to be of paramount importance to developing awareness among health care workers, as well as improving adherence to high-quality clinical practice. This research findings is congruent with the findings of the study carried out by (Rapiti, et al., 2005), who found that he greater awareness of universal precautions among health care workers employed for a longer period non-compliance among medical doctors and nurses are associated with insufficient knowledge, workload, forgetfulness, workplace safety and the insight that colleagues also failed to track.

Personnel protective equipments reduce the risk of exposure of the health care provider’s skin or mucous membranes to potentially infectious materials. Protective barriers reduce the risk of exposure to blood and other body fluids to which universal precautions apply. Examples of protective barriers include gloves, gowns, masks, and protective eyewear. Just over one half of the respondents indicated that they were provided with protective equipment most times. Furthermore, more nurses were provided with protective equipment than medical technologists and medical doctors. Interestingly, more respondents who were aware of universal precautions reported being provided with protective equipment more often than those who were somewhat or not aware. This study results congruent with the research data carried out by Pournaras, et al, 2006, who reported that less than two-thirds of health care workers claimed that they always used personal protective equipment such as aprons, gowns and gloves, during surgeries and while conducting deliveries. According to Jawaid, et al., among medical doctors working in a tertiary care hospital in Pakistan, compliance for hand washing was 86%, for wearing gloves was 79%, masks 46%, eye goggles 25% and for using gowns/plastic aprons was 45%. However, there is sometimes a high rate of non-compliance among health care workers and this may be due to a lack of understanding among health care workers of how to properly use protective barriers.

This study showed that there was high level of awareness towards occupational hazards among orthodontic staff within the study setting. These findings suggest that training of dental staff to maintain and enhance their knowledge about occupational safety, blood borne pathogens and universal precautions could improve their use of universal precautions. Regular training should include the universal precautions, initial biohazard handling, safety policies, safety behavior, safety equipments, continuing monitoring and maintain continuous quality improvement concerning the practice of occupational safety.

3. Acknowledgements

Appreciation is hereby extended to all the participants and administrators staff at the selected dental clinics-Saudi Arabia.
