Abstract: This study aimed to find out the effects of supplementation of wheat bread with food industry by-products, orange peels, at 5%, 7% and 10% levels. The rheological analysis of orange peel showed that maximum resistance to extension was found to be increasing from 496 in wheat flour to 527 mm in wheat flour containing 5% orange peels powder, while increasing the addition of orange peels to 7% caused an increase in dough resistance to extension was 528 and at 10% dough resistance to extension was 403 B.U. The results also indicated that addition of orange peels to wheat flour caused an increase in arrived time and a decrease in dough stability. The bun samples prepared by adding orange peels have lead to increase in the water absorption while the arrival time and dough stability were decreased. So fiber as a food industry by product is recommended to be used as food additives to gain nutritional and healthy benefit.

Keywords: Orange peel Rheological Properties, Extensibility, Farinogram

1. Introduction

An orange is a type of citrus fruit which people often eat. Oranges are a very good source of vitamins, especially vitamin C Romero and Rodriguez (1992). Food processing by products have become an important sanitary problem material to be studied. Such efforts have been made for converting these refused materials into valuable products Tresca (2012).

There are some nutritional wastes such as orange peels that are considered important factors of therapeutic diets and nutrient effect supplying essential nutrient elements such as fiber, vitamin, and mineral to human body. Orange peels are a waste product of orange fruits used for processing. They represent <5% of fresh fruit and have a hard horny shell containing an oily kernel. Khalifa(1998). Citrus is the most abundant crop in the world, 63.95 and 12.53 million tons of orange and lemon products were produced during 2004, respectively Laufenberg(2003). Brazil is the world's leading orange producer, with an output almost as high as that of the next three countries combined (the United States, India, and China).

Dried citrus peels are rich in cellulose, hemicelluloses, proteins and pectin, the fat content is however low Dhillon and Gill (2004). In the citrus processing industry citrus peels is the major solid by-product and comprises around 50% of the fresh fruit weight. Orange peel contains many nutrients like essential oil, protein, fiber, vitamin C etc. The citrus waste can be used as raw material for pectin extraction or in pelletized form for animal feeding. However, the citrus waste has to be dried first, and none of these processes has been found to be very profitable. The aim of the study is to find out the effect of supplementation of wheat bun with various levels of orange peel powder.

2. Material and Method

2.1 Procurement of Material

The materials such as orange, orange peel, wheat flour and packaging material will be procured from the local market of Allahabad.

2.2 Preparation of Samples

The materials used in the present study were brought form the local market. These materials were food industry by-products, orange (Citrus sinenis) peels. Organe peels were well washed and dried at 63°C using a hot air oven. A laboratory grinder was used to give powder. The ingredients which were used in bun making were bought from local market. These ingredients included: wheat flour, compressed baker's yeast, sucrose, salt and shortening.

2.3 Rheological Analysis of Bun Dough

Citrus by-products blends at 0, 5, 7 and 10% levels were prepared by replacing wheat flour. The effect of citrus by-products (orange peel and pulp) on the mixing profile of the dough was studied by two methods Farinograph and Extensograh which were carried in CFTRI, Mysore.

2.3.1. Farinograph Test

Water absorption (amount of water required for the dough to have consistency of 500 Brabender units line), arrival time (the time in minutes for the curve to reach the 500 Brabender unit line after the mixer will be started and water will be added), mixing time (the time in minutes from the first addition of the water to development of dough's maximum consistency), stability (the time in minutes elapsing when the top of the curve interacts first 500 B.U. line leaves that line) and softening of wheat flour dough and its blends with orange peel was determined according to AACC (2000) methods using a Farinograph type (PL) (Barbender Farinograph, Germany). 250 grams of tested samples (14% moisture basis) were used.

2.3.2. Extensograph Test

Extensograph test was carried out according to the method described by AACC (2000) to measure the following data:

- Dough extensibility (E) (the total length of the base of the extensogram measured in millimeters).
- Dough resistance to extension (R) (the height of the extensograph curve was measured in Brabender units after 5 minutes from the start).
- Dough energy (represented by the area in Cm² out lined the curve) and the peak height (the maximum height of the extensograph curve measured in Brabender units).

2.4. Bun Making

Bread was made using the 100 - g straight dough method. The basic formula included 100 g of flour, 2 g of compressed baker's yeast 1 g of sucrose, 2 g of salt, 1 g of shortening, water as needed, and different concentrations of orange peel, which has been added at 5, 7 and 10% concentration on a flour replacement basis. The dough was fermented for 60 min. at 30 °C followed proof period for 15 min. Breads were baked at 230 °C for 25 min.

3. Result and Discussion

3.1 Texture Analysis of Orange Peel Powder Supplemented Bun:

Texture Analysis of Orange Peel Powder Supplemented Bun was done. The product had acceptable quality in the analysis. In texture analysis the force which was applied to the product to check hardness, fracturability, adhesiveness, springiness, cohesiveness, gumminess, chewiness and resilience of the product (bun). Data as shown in fig 4, at 5% level the texture of the product was good.

3.2 Rheological Properties

3.2.1 Farinograph Characteristics

The results in Table 3 showed the effect of addition of orange peels to wheat flour on farinograph readings. From these results it could be noticed that, addition of orange peels, to wheat flour increased dough water absorption, from 49.2, 53.6, 59.3 and 63.0%, for wheat flour and with addition of 0, 5, 7 and 10% of orange peels, respectively. The results also indicated that addition of orange peels to wheat flour caused an increase in arrived time and a decrease in dough stability. Arrived time was found to be 4.8, 4.2, 3.0 and 3.5 min, dough stability was found to be 5.3, 4.2, 4.1, 2.7 min at the levels 0%, 5%, 7% and 10%, respectively. However, mixing tolerance was found to be 52, 76, 52, and 96, at different levels of orange peel addition.
that can be incorporated to develop acceptable bun was 5%.

Evaluation depicts that highest amount of orange peel powder was found to be the best regarding all sensory attributes like color, texture, flavor, and overall acceptability. This was so because the values for all sensory attribute were maximum. The texture parameters are having acceptable results at 5% incorporation of orange peel powder. The results in rheological analysis indicated that addition of orange peels to wheat flour caused an increase in arrived time and a decrease in dough stability in Farinograph and in Extensograph the extensibility of the dough decreased and maximum resistance to extension increased by increasing the levels of nutritional waste in all samples. Similar results were observed by Singh (2013).

### 3.2.2 Extensograph Characteristics

From the results presented in Table 4. It could be noticed that, extensibility of the dough decreased from 137 min in wheat flour to 100 min in wheat flour containing 5%, 7%, 10% orange peels powder, respectively. Maximum resistance to extension was found to be increasing from 496 in wheat flour to 527 mm in wheat flour containing 5% orange peels powder, while increases 528 mm the addition of orange peels to 7% and at 10% decrease in dough resistance to extension to 403 B.U., respectively. The extensibility of the dough decreased and maximum resistance to extension increased by increasing the levels of nutritional wastes in all samples. Similar results were observed by Singh (2013).
