Abstract: It is about the electron, how it transfer energy, when it flows and creates electricity, electron constant energy, intermediate face converter etc.

Keywords: Energetic Electron, Empty Package of Energy

Electron is nothing but an empty package of energy. Not electron but energetic electron (E.g. * = when an electron gets energy called energetic electron) only can flow and able to produce electricity. It acts as a transportation medium of energy and also as an intermediate face conversion medium of two faces of energy (i.e. mechanical energy to light energy).

- Only energetic electron can flow not electron.
- Ordinary electron can only vibrate at its own position with a certain amount of energy. This energy is called electron constant energy.
- When Electron gets extra amount of energy (Energetic Electron) and flows that called electricity.
- Like an empty package of energy, electron stores energy and transfer from one place to another.
- 1st it stores energy, transfers one place to another, uses the energy and again gets empty package as before.
- It also works as a face conversion medium (intermediate face) between 2 faces of energy. Example, mechanical energy to light energy
- Electron can never produce or destroy; the total number of electron is always constant.
