Abstract: This paper investigate the peristaltic transport of a couple stress fluid in an asymmetric and non-uniform channel through the porous medium under the action of an externally applied magnetic field. The effects of slip velocity on the channel walls have been taken into account and the effects particle size. The non-linearity of the problem is analyzed by using the long wavelength and low Reynolds number approximations. The mathematical expressions for axial velocity, stream function, pressure gradient and pressure rise per wave length have been derived analytically. The above said quantities are computed for a specific set of values of the different Parameters involved in the present model. The computational results are presented in the form of graphs. Show that the axial velocity is appreciably influenced by the presence of slip velocity, couple stress parameter, Hartmann number, Darcy number and phase different as well as the non-uniformity of the channel. Show that there is a linear relationship between pressure rise for each wave length and volumetric flow rate. This study puts an important observation that the occurrence of trapping bolus can be eliminated with suitably adjusting couple stress effect and the application of strong magnetic field. The role of slip velocity has a reducing effect on the bolus size. Moreover, the size of the bolus is increased by increasing the Darcy number and non-uniform parameter of the channel.

Keywords: couple stress fluid, slip velocity, peristaltic flow, non-uniform channel, porous medium

1. Introduction

The word peristalsis is derived from the Greek word περισταλτικός, which means clapping and compressing. It is used to describe a progressive wave of contraction along a channel or tube whose cross-sectional area consequently varies. In physiology, peristalsis is used by the body to push or mix the contents of the tube as the ureter passes urine from the kidney to the bladder, the movement of the egg into the fallopian tube, transport of bile in the bile duct and the transfer of sperm in the cervical canal. He also speculated that peristalsis may be involved in transporting water in high trees. Water transfer involves movement through a porous matrix of trees. Some worms use peristalsis as a means of mobility. Usually one encounters such motion in digestive tract such as the human gastrointestinal tract where smooth muscle tissue contracts and relaxes in sequence to produce a peristaltic wave, which propels the bolus (a ball of food) while in the esophagus and upper gastrointestinal tract along the tract. The peristaltic movements not only avoid retrograde motion of the bolus but always keep pushing it in the forward direction, i.e., the important aspect of peristalsis is that it can propel the bolus against gravity effectively. The peristaltic transport of viscous liquids is the most important biomechanical instrument of the digestive system. Over past few decades, peristalsis has attracted much attention of a large class of researchers due to its important engineering and biomedical applications. Akram et al. [1] Influence of Lateral Walls on Peristaltic Flow of a Couple stress fluid in an uniform Rectangular Duct. Ali and Hayat[2] they have studied on the peristaltic flow of a micropolar fluid in an asymmetric channel by considering different kind of fluid models, wherein they found distinguishable effect of phase difference of wall motion on velocity and other flow characteristics. Ellahi et al. [3] presented a theoretical study on peristaltic flow of Couple stress fluid in a symmetric non-uniform channel with compliant walls without examining the effects of magnetic field and slip boundary conditions. It has been proposed that boundary slip in aqueous systems is favored by hydrophobic surfaces in order to reduce the liquid-solid friction. Moreover, surface roughness and non-uniformity of the channel may also play a vital role in boundary slip. The problem of mechanism of peristaltic transport has been rigorously studied by Fung and Yih [4]. Latham[ 5 ] who first introduced the motion of fluids in the peristaltic pump. Lozano [6] Peristaltic Flow with Application to Ureteral Biomechanics. Maiti and Misra [7] a theoretical investigation of the peristaltic transport of a couple stress fluid in a porous channel. The study is motivated towards investigating the physiological flow of blood in the micro-circulatory system. Mishra and Rao [8] Peristaltic transport of a Newtonian fluid in an asymmetric channel. Rathod and Sanjeevkumar [9] An analysis of peristaltic flow of a couple-stress fluid, with immersed nanoparticles, in an asymmetric channel having flexible walls. The idea of pumping characteristics was first introduced by Shapiro et al. [10] that the pumping is determined through the variation in time averaged flux with difference in pressure across one wave length. Shit and Ranjit [11] investigation of peristaltic transport of a couple stress fluid in an asymmetric and non-uniform channel under the action of an externally applied magnetic field. Shit et al. [12] studied the effect of induced magnetic field on the peristaltic transport in an asymmetric channel by considering micro polar fluid model. Their study reveals that the consideration of induced magnetic field has significant impact on velocity profile, pressure rise per wave length as well as on stream lines. The study is motivated towards investigating the peristaltic mechanism in the digestive system by considering the particle size effects . Interaction of couple stresses and velocity slip on peristaltic transport in uniform and non-uniform symmetric channel studied analytically by Sobh [13] without considering the effect of magnetic field. The couple stress fluid may be considered as...
a special case of non-Newtonian fluid which is intended to take into account the particle size effects. To characterize the couple stress fluid, Stokes [14] gave a concept of constitutive relationship between the stress and strain rate in micro-continuum theory of fluids which allows for polar effects such as the presence of couple stresses, body couples and a non-symmetric stress tensor. The constitutive equations in these fluid models are very complex because of the involvement of various material constants leading to a boundary value problem so that the order of the differential equations is higher than the Navier-Stokes equations. He found that pressure rise is greater for a couple stress fluid than a Newtonian fluid model under similar circumstances. It is well known that, if the flow is steady in the wave frame the instantaneous pressure difference between two stations of one wave length apart is a constant. Tripathi [15] Investigated Peristaltic Hemodynamic Flow of Couple-Stress Fluids through a porous medium with slip effect. Weinberg et al. [16] carried out experimental investigations of a two-dimensional peristaltic flow induced by sinusoidal waves. Fluids through a porous medium with slip effect. Weinberg et al. [16] carried out experimental investigations of a two-dimensional peristaltic flow induced by sinusoidal waves. Their work was concerned with the measurements of mean flow, pressure gradient and pressure rise under low Reynolds number approximations. Therefore, our motivation is to examine the role of boundary slip when the non-uniform channel walls contracting and expanding. Owing to the abovementioned studies, we have investigated the effect of slip velocity on peristaltic flow of a couple stress fluid through an asymmetric and non-uniform channel through the porous medium. The long wave length and low Reynolds number assumptions have been made to simplify the governing equations. The present analysis could be used for the design of instruments for transportation mechanism in the digestive system of humans and animals.

2. Mathematical Formulation and Solution

Consider the peristaltic transport of an incompressible couple-stress fluid through an asymmetric and non-uniform two-dimensional channel with porous medium under the action of an external magnetic field: generated by propagation of waves on the channel walls travelling with different amplitudes and phases but with constant speed c (see Fig.1).

Let \( Y' = h_1'(X', t') \) and \( Y' = h_2'(X', t') \) represent respectively the upper wall and lower wall of the channel, such that

\[
h_1'(X', t') = d_1 + (X' - c t') \tan \alpha + a_2 \cos \frac{\pi}{\lambda}(X' - \alpha t' + \phi)
\]  

(1)

\[
h'_2(X', t') = d_2 - (X' - c t') \tan \alpha + a_2 \cos \frac{\pi}{\lambda}(X' - \alpha t' + \phi)
\]

(2)

Where \( a_1 \) and \( a_2 \) are the amplitudes of waves, \( \lambda \) is the wave length, \( \phi (0 \leq \phi \leq \pi) \) the phase difference between the channel walls, \( X' \) and \( Y' \) are the rectangular Cartesian coordinates with \( X' \) measures the axis of the channel and \( Y' \) the transverse axis perpendicular to \( X' \). \( d_1' \) and \( d_2' \) are the constant height of the upper wall and lower wall of the channel and \( \alpha \) denotes the inclination of the channel walls with the central axis- \( X' \). The system is stressed by an external transverse uniform constant magnetic field of strength \( B_0 \). Due to the imposition of an external magnetic field in an electrically conducting fluid, there arises electromotive force (emf) inducing a current inside the flow region. Since the electrical conductivity of liquid is very small, the magnetic Reynolds number becomes too small. Therefore, we have neglected the induced electrical filed as well as induced magnetic field.

The equations of motion for unsteady flow through an asymmetric channel of an incompressible couple stress fluid (cf. Stokes [14]) with externally imposed magnetic field by neglecting the body couples are,

\[
\nabla \cdot \mathbf{V} = 0
\]

(3)

\[
\rho \left( \frac{\partial \mathbf{V}}{\partial t'} + \mathbf{V} \cdot \nabla \mathbf{V} \right) = -\nabla p' + \mu \nabla^2 \mathbf{V} - \eta \frac{\partial \mathbf{V}}{\partial t'} + \mathbf{j} \times \mathbf{B}
\]

(4)

\[
\rho \left( \frac{\partial \mathbf{u}'}{\partial t'} + \mathbf{V} \cdot \nabla \mathbf{u}' \right) = -\nabla P' + \mu \nabla^2 \mathbf{u}' - \eta \frac{\partial \mathbf{u}'}{\partial t'} + \mathbf{j} \times \mathbf{B} + (\mathbf{j} \times \mathbf{B}) \times \mathbf{B} \]

(5)

\[
\rho \left( \frac{\partial \mathbf{v}'}{\partial t'} + \mathbf{V} \cdot \nabla \mathbf{v}' \right) = -\nabla P' + \mu \nabla^2 \mathbf{v}' - \eta \frac{\partial \mathbf{v}'}{\partial t'} + (\mathbf{j} \times \mathbf{B}) \times \mathbf{B}
\]

(6)

where \( \mathbf{V}' \) is the velocity vector, \( P' \) the fluid pressure, \( \rho \) the fluid density, \( \mu \) the dynamic viscosity of the fluid, \( \eta \) is the constant associated with couple stress effect, \( B_0 \) the magnetic field vector, \( E' \) the electric field vector and \( \sigma \) denotes the electrical conductivity of the fluid. The last term appearing in Eq. (4) is the magnetic body force per unit volume in which \( \mathbf{j} = \sigma (\mathbf{E}' + \nabla \times \mathbf{B}') \) represents the Lorentz force arising from Maxwell’s equations of electromagnetism and \( \nabla^2 = \frac{\partial^2}{\partial x^2} + \frac{\partial^2}{\partial y^2} \)

\[
\nabla^2 = \frac{\partial^2}{\partial x^2} + 2 \frac{\partial^2}{\partial x \partial y} + \frac{\partial^2}{\partial y^2}
\]

It is further noticed that the flow field in laboratory frame \( (X', Y') \) and wave frame \( (x', y') \) are treated as unsteady and steady motion respectively. Considering the relation between the wave frame \( (x', y') \) moving with a constant speed \( c \) away from a fixed frame \( (X', Y') \) that follows from the following transformations.In addition to equation (5) and (6) become

\[
\frac{\partial \mathbf{V}}{\partial t'} + \mathbf{V} \cdot \nabla \mathbf{V} = -\nabla P' + \mu \nabla^2 \mathbf{V} - \eta \frac{\partial \mathbf{V}}{\partial t'} + \mathbf{j} \times \mathbf{B}
\]

(7)

\[
\frac{\partial \mathbf{u}'}{\partial t'} + \mathbf{V} \cdot \nabla \mathbf{u}' = -\nabla P' + \mu \nabla^2 \mathbf{u}' - \eta \frac{\partial \mathbf{u}'}{\partial t'} + \mathbf{j} \times \mathbf{B} + (\mathbf{j} \times \mathbf{B}) \times \mathbf{B}
\]

(8)

\[
\frac{\partial \mathbf{v}'}{\partial t'} + \mathbf{V} \cdot \nabla \mathbf{v}' = -\nabla P' + \mu \nabla^2 \mathbf{v}' - \eta \frac{\partial \mathbf{v}'}{\partial t'} + (\mathbf{j} \times \mathbf{B}) \times \mathbf{B}
\]

(9)

\[
\frac{\partial \mathbf{v}'}{\partial t'} + \mathbf{V} \cdot \nabla \mathbf{v}' = -\nabla P' + \mu \nabla^2 \mathbf{v}' - \eta \frac{\partial \mathbf{v}'}{\partial t'} + (\mathbf{j} \times \mathbf{B}) \times \mathbf{B}
\]

(10)
\[
\frac{\partial u'}{\partial t} = 0, \quad \frac{\partial v'}{\partial t} = 0
\]

\[
v'(x', y') = V', \quad y' = Y' - ct', U' = u'(x', y')
\]

In which \((u', v')\) and \((U', V')\) are respectively the velocity components in the wave and laboratory frames. Using the abovementioned transformations, the governing Eqs. (3) and (5) can be written in the wave frame of reference as:

\[
\rho \left( (u' + c) \frac{\partial u'}{\partial x'} + v' \frac{\partial u'}{\partial y'} \right) = -\frac{\partial P'}{\partial x'} + \mu \nabla^2 u' - \eta \nabla^4 u' + cB_2^2 (u' + c) - \frac{\mu}{k_0} u' \tag{8}
\]

\[
\rho \left( (u' + c) \frac{\partial v'}{\partial x'} + v' \frac{\partial v'}{\partial y'} \right) = -\frac{\partial P'}{\partial y'} + \mu \nabla^2 v' - \eta \nabla^4 v' + \frac{\mu}{k_0} v' \tag{9}
\]

Let us introduce the following non-dimensional variables (cf. Mishra and Rao[8]).

\[
P, t \rightarrow \frac{ct}{\lambda}, \quad \psi = \frac{v'}{c_1}, \quad \omega = \frac{\lambda}{\alpha} \frac{d_1}{d_2} \frac{P'(x)}{\kappa \mu}
\]

\[
u = \frac{\nu'}{c_1}, \quad h_1(\xi) = \frac{h_1(\xi)}{d_1} = 1 + \left( \frac{\tan \alpha}{\xi} \right) x + \frac{a_1}{d_1} \cos (2\pi \xi) \tag{10}
\]

\[
h_2(\xi) = \frac{h_2(\xi)}{d_1} = -\frac{d_2}{d_1} - \left( \frac{\tan \alpha}{\xi} \right) x + \frac{a_1}{d_1} \cos (2\pi \xi + \phi) \tag{11}
\]

where \(\psi\) represents the dimensionless stream function in which the velocity components \(u\) and \(v\) given by \(u = \frac{\partial \psi}{\partial y}\) and \(v = -\frac{\partial \psi}{\partial x}\) satisfying the continuity Eq. (7).

Using the non-dimensional variables defined in Eqs. (8), (9), (10) and (11) transformed into following equations in terms of stream function \(\psi\) as:

\[
Re \delta \left( \frac{\partial \psi}{\partial y} \frac{\partial \psi}{\partial x} - \frac{\partial \psi}{\partial x} \frac{\partial \psi}{\partial y} \right) + \frac{\partial^2 \psi}{\partial x^2} \frac{\partial^2 \psi}{\partial y^2} \right) = -\frac{\partial P}{\partial x} + \frac{\partial^2 \psi}{\partial x^2} \frac{\partial^2 \psi}{\partial y^2} \right)
\]

The non-dimensional parameters that appeared in Eqs. (12) and (13) are defined as \(Re = \frac{cd_1}{\mu}\) the Reynolds number, \(\delta = \frac{d_1}{\lambda}\) the Wave number, \(H_3 = B_d d_1 \sqrt{\rho \mu}\) the Hartmann number, \(\gamma = \frac{d_1}{\sqrt{\rho \mu}}\) the couple stress parameter and \(Da = \frac{h_2}{d_1}\) the Darcy number.

The instantaneous volumetric flow rate in the laboratory frame is given by

\[
Q = \int_{-h_1}^{h_2} U(x', y', t') dy' \tag{14}
\]

Similarly, the rate of volume flow in the wave frame is obtained as

\[
q = \int_{-h_1}^{h_2} u'(x', y') dy' \tag{15}
\]

Using the frames transformation into Eqs. (14) and (15), the relation between \(Q\) and \(q\) can be obtained as

\[
Q = q + c(h_1 - h_2) \tag{16}
\]

The time mean flow over a period \(T\) at a fixed position \(X'\) is defined as

\[
Q' = \frac{1}{T} \int_{0}^{T} Q dt \tag{17}
\]

Using Eq. (16) in Eq. (17) the flow rate \(Q'\) has the form

\[
Q' = \frac{1}{T} \int_{0}^{T} q dt + c(h_1 - h_2) = q + cd_1 + c d_2
\]

\[+ 2c x_1 \frac{\tan \alpha}{d_1} + c a_1 \cos (2\pi x) + c a_2 \cos (2\pi x + \phi) \tag{18}
\]

where \(a = \frac{c_1}{d_1}, b = \frac{c_2}{d_2}, d = \frac{a_1}{d_1}, k = \frac{\tan \alpha}{d_1}\) is called the non-uniform parameter of the channel.

The non-dimensional form of Eq. (18) is now given by

\[
\frac{\theta = F + 1 + \phi + 2k x + a \cos (2\pi x) + b \cos (2\pi x + \phi)}{\theta = \psi(h_1) - \psi(h_2)} \tag{21}
\]

Under the assumption of long wave length approximation \((\delta \ll 1)\) and low Reynolds number, \((Re \ll 1)\) (cf. Shapiro et al.[10]) eliminating pressure term using cross differentiation from the dimensionless Eqs. (12) and (13) one can write in a single differential equation in terms of stream function \(\psi\) as

\[
\frac{\delta^2 \psi}{\partial y^2} - \frac{\delta^4 \psi}{\partial x^2 \partial y^2} + H_3^2 \frac{\partial^2 \psi}{\partial y^2} + \frac{\delta^2 \psi}{\partial x^2} + \frac{\delta^2 \psi}{\partial x^2} + \frac{\delta^2 \psi}{\partial y^2} + 0 = 0 \tag{23}
\]

The boundary conditions in terms of the stream function \((x, y)\) in the wave frame can be written as
couple stress parameter accelerating effect near the channel walls for increasing decelerating the fluid motion. Similarly the axial velocity has external magnetic field, which plays a vital role in the Lorentz force that arises due to the application of an number in the central region of the channel with increasing Hartmann number number couple stress parameter channel for different values of the Hartmann number

\[
\frac{\partial \psi}{\partial y} + \beta \frac{\partial^2 \psi}{\partial y^2} = -1 \quad \text{on } y = h_1
\]

\[
\frac{\partial \psi}{\partial y} + \beta \frac{\partial^2 \psi}{\partial y^2} = -1 \quad \text{on } y = h_2
\]

\[
\psi = \frac{F}{2} y \quad \text{on } y = h_1
\]

\[
\psi = \frac{F}{2} y \quad \text{on } y = h_2
\]

\[
\frac{\partial^2 \psi}{\partial y^2} = 0 \quad \text{on } y = h_1 \text{ and } y = h_2
\]

The solution of (23) satisfying the corresponding boundary conditions (24) is

\[
\psi = \frac{1}{4} \sqrt{\Delta \alpha} \left( \frac{e^{-\alpha_0 y} c_1}{a_3} - \frac{e^{\alpha_0 y} c_2}{a_3} + \frac{e^{\alpha_2 y} c_3}{a_4} + \frac{e^{-\alpha_2 y} c_4}{a_4} \right) + c_5 + y c_6
\]

The velocity can be written as

\[
u = \frac{1}{4} \sqrt{\Delta \alpha} \left( \frac{e^{-\alpha_0 y} c_1}{a_3} - \frac{e^{\alpha_0 y} c_2}{a_3} + \frac{e^{\alpha_2 y} c_3}{a_4} + \frac{e^{-\alpha_2 y} c_4}{a_4} \right) + c_6
\]

Once we determined the stream function \( \psi \), the axial pressure gradient can be obtained as

\[
\frac{\partial p}{\partial y} = 0
\]

\[
\frac{\partial p}{\partial x} = \frac{\partial^2 \psi}{\partial y^2} + \frac{1}{y^2} \frac{\partial^2 \psi}{\partial y^2} = \frac{H_a^2}{\Delta \alpha} \left( \frac{\partial \psi}{\partial y} + 1 \right) - \frac{1}{\Delta \alpha} \frac{\partial \psi}{\partial y}
\]

The pressure rise per wave length \( \Delta p \) in non-dimensional form is defined by

\[
\Delta p = \int_0^1 \frac{\partial p}{\partial x} \, dx
\]

3. Results and Discussion

The analytical expressions for the axial velocity, pressure gradient, pressure rise and stream function are derived in this section. The numerical results corresponding to the abovementioned analytical expressions have been computed using MATHEMATICA subject to the following data:

\[
\Delta \alpha = 0.1, 0.2 \text{ and } 0.6 , H_a = 0.1, 0.2 \text{ and } 1.8 , b = 0.4 , a = 0.5, \gamma = 2, 2.3 \text{ and } 2.8 , \beta = 0.1, 0.2 \text{ and } 0.5 , k = 0.2, 0.3 \text{ and } 0.6
\]

3.1 Velocity distribution

Figs. 2-7 represent the variation of axial velocity \( u \) across the channel for different values of the Hartmann number \( H_a \), couple stress parameter \( \gamma \), the slip parameter \( \beta \), the Darcy number \( \Delta \alpha \), phase difference \( \phi \) and the non-uniform parameter \( k \). Fig. 2 shows that the axial velocity decreases in the central region of the channel with increasing Hartmann number \( H_a \), while the axial velocity increases in the boundary of the channel wall. The reason behind this fact is the Lorentz force that arises due to the application of an external magnetic field, which plays a vital role in decelerating the fluid motion. Similarly the axial velocity has reducing effect at the central region of the channel and accelerating effect near the channel walls for increasing couple stress parameter \( \gamma \) as shown in Fig. 3. In this case velocity decreases due to the increase of particle size suspended in the fluid itself and causes flattening of the velocity profiles. In order to satisfy the conservation of mass, the flow rate remains same for any value of these parameters at any cross section of the channel. From Fig. 4 shows that the axial velocity decreases in the central region of the channel with increasing the slip parameter \( \beta \), while the axial velocity increases near the channel walls. This fact is influenced by the presence of velocity slip at the walls for which the axial velocity is faster at the peripheral region than in its core region. Therefore the slip effect has also significant impact on the axial velocity. It reduces the force of friction at the wall and propel to fluid flow accurately. From Fig. 5 we observed that the axial velocity also decreases at the central region with increasing the non-uniform parameter \( k \) of the channel, while the axial velocity increases in the boundary of the channel wall. It is examined in Fig.6 that by increasing phase difference \( \phi \), the velocity of fluid decreases in the region \( yc[-1.5,-0.3] \), whereas it increases in the rest of region. Fig. 7 we observed that the axial velocity increase at the central region with the increase of the Darcy number \( \Delta \alpha \), while the axial velocity decreases in the boundary of the channel wall.

\[
\frac{\partial \psi}{\partial y} = 0
\]

\[
\frac{\partial p}{\partial x} = \frac{\partial^2 \psi}{\partial y^2} + \frac{1}{y^2} \frac{\partial^2 \psi}{\partial y^2} = \frac{H_a^2}{\Delta \alpha} \left( \frac{\partial \psi}{\partial y} + 1 \right) - \frac{1}{\Delta \alpha} \frac{\partial \psi}{\partial y}
\]

\[
\Delta p = \int_0^1 \frac{\partial p}{\partial x} \, dx
\]
the Hartmann number \( H_a \), couple stress parameter \( \gamma \), the slip parameter \( \beta \), Darcy number \( Da \), phase different \( \phi \) and the non-uniform parameter \( k \). The whole region is considered into five parts (i) peristaltic pumping region where \( (\Delta \rho > 0, F > 0) \). (ii) augmented pumping(co-pumping) region where \( (\Delta \rho < 0, F > 0) \). (iii) when \( (\Delta \rho > 0, F < 0) \), then it is a retrograde pumping region. (iv) There is a co-pumping region where \( (\Delta \rho < 0, F < 0) \). (v) \((\Delta \rho = 0)\) corresponds to the free pumping region. Fig. 14 shows that pressure rise \( \Delta p \) increases with increasing Hartmann number \( H_a \). It can be seen from the graph that in a retrograde region \( (\Delta \rho > 0, F < 0) \), the pumping rate decreases in a co-pumping region where \( (\Delta \rho < 0, F < 0) \) with an increase in \( H_a \). Fig. 15 shows that pressure rise \( \Delta p \) decreases with increasing Darcy number \( Da \). It is observed the pumping increases in the region of augmented pumping and the co-pumping region \( (\Delta \rho < 0) \).

Fig. 16 shows that pressure rise \( \Delta p \) decreases with increasing couple stress parameter \( \gamma \). It is observed that in a retrograde pumping region \( (\Delta \rho > 0, F < 0) \), the pumping rate increases in a co-pumping region where \( (\Delta \rho < 0) \) with an increase in \( \gamma \). Fig. 17 shows that pressure rise \( \Delta p \) decreases with increasing slip parameter \( \beta \). It is observed that in a retrograde pumping region \( (\Delta \rho > 0, F < 0) \), the pumping rate increases in a co-pumping region where \( (\Delta \rho < 0) \) with an increase in \( \beta \). Fig. 18 shows that pressure rise \( \Delta p \) decreases with increasing non-uniform parameter \( k \). It is observed that the pumping rate increases in the co-pumping region \( (\Delta \rho < 0) \) and free pumping region \( (\Delta \rho = 0) \). Fig. 19 shows that pressure rise \( \Delta p \) increases with increasing phase different \( \phi \) in a retrograde pumping region. It is observed that the pumping rate decreases in the co-pumping region \( (\Delta \rho < 0) \) with an increase in the phase different \( \phi \). It is noticed that there is a linear relationship between pressure rise for each wave length and volumetric flow rate.

\[ \gamma = 2, \phi = \frac{\pi}{4}, F = 1, k = 0.2, x = 1 \]

\[ d = 1, \phi = \frac{\pi}{4}, F = 1, \beta = 0.1, x = 1 \]

3.2 Pumping characteristics

Figs. 8-13 illustrate the variation of axial pressure gradient along the Length of the channel in one wave length \( x \in [0,1] \).

From these figures one can note that through the region \( x \in [0.2,0.8] \), i.e. the narrowing part of the channel, flow cannot pass easily. Therefore, it requires more pressure gradient to make it as normal flow. Similarly in the wider part of the channel, i.e. in the region \( x \in [0.02] \cup [0.8,1] \) fluid can pass easily because of the lower pressure gradient. Fig. 8 we observed that the magnitude of the axial pressure gradient increasing with the increase of the Hartmann number \( H_a \).

From this figure, it may point out that when the applied magnetic field is high, then more pressure is needed to pass the same volume of fluid in the narrowing part of the channel. However, the trend is reversed in the case of the Darcy number \( Da \), slip parameter \( \beta \), couple stress parameter \( \gamma \), phase different \( \phi \) as well as non-uniform parameter \( k \) of the channel as shown in Figs. 9-13 respectively. Therefore, the less pressure is required to fluid flow.

Figs 14-19 depict the variation of pressure rise in function of volumetric flow rate in the wave frame for different values of

\[ \frac{\partial p}{\partial x} \]

\[ \frac{\partial p}{\partial x} \]

\[ \frac{\partial p}{\partial x} \]

\[ \frac{\partial p}{\partial x} \]
Figure 10: Distribution of pressure gradient $\delta p = \frac{dp}{dx}$ for different values of $\beta$ with $Da = 0.1, H_a = 0.1, \gamma = 2$, $a = 0.5, b = 0.4, d = 1, \phi = \frac{\pi}{4}, F = 1, k = 0.2, y = 1$

Figure 11: Distribution of pressure gradient $\delta p = \frac{dp}{dx}$ for different values $\gamma$ with $Da = 0.1, H_a = 0.1, a = 0.5, b = 0.4, d = 1, \beta = 0.1, \phi = \frac{\pi}{4}, F = 1, k = 0.2, y = 1$

Figure 12: Distribution of pressure gradient $\delta p = \frac{dp}{dx}$ for different values $\phi$ with $Da = 0.1, H_a = 0.1, \gamma = 2, a = 0.5, b = 0.4, d = 1, \beta = 0.1, F = 1, k = 0.2, y = 1$

Figure 13: Distribution of pressure gradient $\delta p = \frac{dp}{dx}$ for different values of $k$ with $Da = 0.1, H_a = 0.1, a = 0.5, b = 0.4, d = 1, \beta = 0.1, \phi = \frac{\pi}{4}, F = 1, \gamma = 2, y = 1$

Figure 14: Variation of pressure rise $\Delta P$ with $F$ for different values of $H_a$ when $Da = 0.1, \gamma = 2, a = 0.5, b = 0.4, d = 1, \beta = 0.1, \phi = \frac{\pi}{4}, k = 0.2, y = 1$

Figure 15: Variation of pressure rise $\Delta P$ with $F$ for different values of $Da$ when $\phi = \frac{\pi}{4}, H_a = 0.1, a = 0.5, b = 0.4, d = 1, \beta = 0.1, \gamma = 2, k = 0.2, y = 1$

channel. We observed that as the non-stream lines with the non-size may help to prevent possible damage of red cells and downstream direction. The phenomenon of reducing bolus decreases in size and transported and disappears in the distribution of stream lines are shown in Figs.23(a, b, c) The presence of sufficiently strong magnetic field. Figs. 20(a, b, c) give the variation of stream lines with the variation of the Hartmann number $H_a$. We have observed that as the Hartmann number increases the trapped bolus also increases in size and transported in the downstream direction. These figures indicate that in the wider part of the channel, the flow is pulled by the wall, whereas in the a narrow part, the fluid is pushed away from the wall.

3.3 Trapping phenomena

It is known that the phenomenon of trapping is the formation of circulating bolus of the fluid is a region of closed stream lines that move with the wave speed in the wave frame. Owing to the trapping phenomenon, there will exist stagnation points, where both the velocity components of the fluid vanish in the wave frame. It is more necessary to study the stream lines pattern, because of the fact that the difference between the values of the stream function at any two points is used to calculate the flux of fluid or volumetric flow rate through a line connecting the two points. It is observed from Figs.20-24 that the bolus formation takes place on both sides of the central line of the channel in the expanded region. As the magnetic field strength increases the size of the trapped bolus decreases and vanishes in the presence of sufficiently strong magnetic field. Figs. 20(a, b, c) give the variation of stream lines with the variation of the Darcy number $D_a$. We have observed that as the Darcy number $D_a$ increases the bolus size decreases. Figs. 21(a, b, c) give the variation of stream lines with the variation of the Darcy number $D_a$. We have observed that as the Darcy number $D_a$ increases the bolus size increase. Figs. 22 (a, b, c) We have observed that as the couple stress parameter $\gamma$ increases the bolus size decreases and disappears at $\gamma = 2.8$. The effects of slip parameter on the distribution of stream lines are shown in Figs.23(a, b, c) The slip parameter also reduces the formation of trapped bolus. We observed that increase of the slip parameter $\beta$ the trapped bolus decreases in size and transported and disappears in the downstream direction. The phenomenon of reducing bolus size may help to prevent possible damage of red cells and other constituents. Figs.24.(a, b, c) illustrate the Variation of stream lines with the non-uniformity $k$ of the asymmetric channel. We observed that as the non-uniform parameter $k$
4. Conclusions

In this paper, we have theoretically studied the effects of slip velocity in a peristaltic transport of physiological fluids represented by non-Newtonian fluid model passing through an asymmetric non-uniform channel with porous medium under the long wave length and low Reynolds number assumptions. In this investigation, special emphasis has been paid to study such as velocity distribution, the pumping characteristic and the trapping phenomena on the basis of a simple analytical solution.

1) The axial velocity (u) at the central region decreases with the increasing values of the Hartmann number (Hₐ), couple stress parameter (γ), the slip parameter (β) and non-uniform parameter (k) of the channel, whereas it increases in the boundary of the channel wall.

2) The axial velocity (u) at the central region increases with the increasing values of the Darcy number (Da), whereas it decreases in the boundary of the channel wall.

3) The axial pressure gradient (\( \frac{dp}{dx} \)) increases with the increase of Hartmann number (Hₐ), whereas it decreases with the increasing values of the Darcy number (Da) and slip parameter (β), couple stress parameter (γ) as well as non-uniform parameter (\( \phi \)) of the channel.

4) There is a linear relationship between pressure rise for each wave length and volumetric flow rate.

5) The pressure rise increases in retrograde pumping with the increasing values of the Darcy number (Da) and \( \phi \), whereas it decreases with the increasing values of the Darcy number (Da) and the non-uniform parameter (k) of the channel.

6) It may interesting to note that the trapped bolus can be eliminated with the increasing values of couple stress parameter (γ) and the application of strong magnetic field. The role of slip velocity (β) has a reducing effect on the bolus size, whereas it increases the bolus size with the increasing values of the Darcy number (Da) and the non-uniform parameter (k) of the channel.
