Abstract: A Balinese woman, 60 years old complaint of hematemesis and melena. Esophagastroduodenoscopy performed one day after admission and revealed a soliter ulcer at duodenum bulb. Histopathology examination revealed a spherical like organism suspected Helicobacter pylori (H. pylori) infection. Eradication of H. pylori by triple drug consisting of omeprazole, amoxicillin and clarithromycin as the standard protocol of eradication within 14 days. Reevaluation by esophagastroduodenoscopy examination will perform in the next 3 months to evaluate the treatment successfully.

Keywords: peptic ulcer, duodenum, H. pylori

1. Background

Approximately 500,000 persons develop peptic ulcer disease in the United States each year. In 70 percent of patients it occurs between the ages of 25 and 64 years. The annual direct and indirect health care costs of the disease are estimated at about $10 billion. However, the incidence of peptic ulcers is declining, possibly as a result of the increasing use of proton pump inhibitors and decreasing rates of Helicobacter pylori (H. pylori) infection. H. pylori, a gram-negative, helical, rod-shaped bacterium, colonizes the gastric mucosa of approximately one-half of the world population and an estimated 30% to 40% of the US population. H. pylori is present in 95% of patients with duodenal ulcers and in 70% of those with gastric ulcers. It is typically transmitted via the fecal-oral route during early childhood and persists for decades. The bacterium is a known cause of gastric and duodenal ulcers and is a risk factor for mucosa-associated lymphoid tissue (MALT) lymphoma and gastric adenocarcinoma.

2. Case Presentation

Female, 60 years old, Balinese, came with chief complaint of hematemesis since one day prior to admission. Patient also complaint of melena since 1 week ago. No history of taking analgetic or NSAIDs. The patient has felt nausea, and abdominal discomfort since 1 month ago. Pain in the middle of abdomen and getting worse at night, do not getting better by antacid. There was no decreased of body weight and using analgetic or NSAIDs. We also did not find any alcohol and smoking history nor previous illness such as diabetes mellitus and cardiovascular diseases not reported.

On physical examination, it was found that her blood pressure was normal: 110/80 mmHg, pulse rate 88 times/minute, respirator rate 18x/minute. Tenderness on palpation of epigastrium. Laboratory result showed a normal on cell blood count: WBC: 8x 10³, Hemoglobin: 10 gr/dl, platelet: 156x10⁵. Liver function test and kidney function test were also normal. The patient diagnosed with hematemesis suspect peptic ulcer. The patient was then admitted to ward and giving infusion ringer lactat, proton pump inhibitor esomeprazole bolus 40 mg intravenous and continuous with 8 mg/ hours and planned for esofagastroduodenoscopy to evaluate the source of hematemesis.

Figure 1: Soliter ulcer at duodenal bulb

Esophagastroduodenoscopy result: Oesophagus was normal, there was a soliter ulcer on duodenum bulb. The diagnosis was soliter ulcer on duodenum bulb. Biopsy done in the duodenum area. The specimen evaluated by Pathology Anatomy Specialist. Biopsy result revealed discontinuity of duodenum superficial epithel mucosa, a lot of polymorfonuclear and limfoplasmacytic cells. Also found spherical and rod like organism. Inferred: duodenum ulcer and found Helicobacter pylori like organism.

Peptic ulcer disease (PUD) may or may not have symptoms. Peptic ulcers can be broadly classified into Gastric or stomach ulcer and Duodenal Ulcer. PUD is one of the most common human ailments, affecting approximately 50% of the world population. Gastric Ulcers occur mainly in the elderly, on the lesser curve. Ulcers elsewhere are often malignant. Duodenal Ulcers are four fold commoner than gastric ulcer.  

3. Discussion

The stomach and the duodenal lining have several mechanisms that prevent ulcers developing. A coating of mucus protects the stomach lining from the effects of acidic digestive juices. Food and other substances in the stomach neutralize acid. Certain chemicals produced by the stomach protect the cells lining the stomach. Peptic Ulcers can be broadly classified into Gastric or stomach ulcer and Duodenal Ulcer. PUD is one of the most common human ailments, affecting approximately 50% of the world population. Gastric Ulcers occur mainly in the elderly, on the lesser curve. Ulcers elsewhere are often malignant. Duodenal Ulcers are four fold commoner than gastric ulcer. Peptic ulcer disease (PUD) may or may not have symptoms. When the symptoms occur, they include a burning pain in the middle or upper stomach between meals or at night, bloating, heart burn, nausea or vomiting. In severe cases, the symptoms include dark or black stool, vomiting of blood, weight loss and severe pain in the mid to upper abdomen. In this case we found hematemesis and also melena, pain usually at night, approximately 4 hours after meal.

Etiology of PUD include H.pylori infection, NSAIDS, peptin, smoking, alcohol,bile-acids, steroids, stress, and changes in gastric mucin consistency (may be genetically determined). Other causes include Zollinger-Ellison syndrome, Crohn disease and liver cirrhosis, and similar symptoms stomach cancer, coronary heart disease, and inflammation of the stomach lining or gallbladder. Symptoms of PUD are nonspecific and diagnosis is unreliable on history, frequent symptoms include, epigastric pain, nausea, flatulence and bloating, heartburn, a posterior ulcer may cause pain radiating to the back. Symptoms in this case, we suspected the cause of duodenum ulcer is H. pylori infection, because on the histopathology examination we found spherical or rod like organism. H. pylori cause PUD at first by infection. Then it causes gastritis in the antral region. Then there is a defective inhibition of gastrin release and acid secretion. The gastric acid is then hyper secreted. The duodenal acid load is increased. This is followed by metaplasia in the duodenal bulb. Thus duodenal H. pylori infection is caused. Peptic ulcers can heal spontaneously and may occur intermittently. But they can also have a serious fate. The complications might be life threatening without any warning signs. This is most common in elderly patients on NSAID. The most complication that occur include bleeding and perforation. Bleeding can be both gradual and abrupt. If abrupt bleeding occurs, it causes black, tarry stools and a drop in blood pressure. Only about 2 to 5 percent of people with a peptic require surgery. Perforation usually causes abdominal pain suddenly and usually requires surgery.

If the initial clinical presentation suggests the diagnosis of peptic ulcer disease, the patient should be evaluated for alarm symptoms. Anemia, hematemesis, melena, or hemepositive stool suggests bleeding, vomitting suggests obstruction, anorexia or weight loss suggests cancer persisting upper abdominal pain radiating to the back suggests penetration; and severe, spreading upper abdominal pain suggests perforation. Patients older than 55 years and those with alarm symptoms should be referred for prompt upper endoscopy. Esophagogastroduodenoscopy (EGD) is more sensitive and specific for peptic ulcer disease than upper gastrointestinal barium studies and allows biopsy of gastric lesions. Presence of H. pylori can be confirmed with a serum enzyme-linked immunosorbent assay (ELISA), urea breath test, stool antigen test, or endoscopic biopsy. Eradicating H. pylori is often sufficient in patients with small duodenal ulcers. We do esophagogastroduodenoscopy in this case one day after admission. the biopsy performed in the duodenum area, to know the cause of ulcer. Before endoscopy performed, we give treatment proton pump inhibitor infusion, bolus 80 mg and then continues with 8 mg/hour until 72 hours. Antacid and also sucralfat given to this patient.

The 2015 European Society of Gastrointestinal Endoscopy guideline made a strong recommendation with high-quality evidence for intravenous bolus with continuous PPI infusion for 72 hours in patients with endoscopic hemostasis and for patients not receiving endoscopic hemostasis with adherent clot. The organization suggests that intermittent intravenous bolus dosing (at least twice daily) for 72 hours postendoscopy may be considered, with a weak recommendation and moderate-quality evidence. Patients with over upper gastrointestinal bleeding. Hemodynamic status is first assessed, and resuscitation initiated as needed. Patients are risk-stratified based on features such as hemodynamic status, comorbidities, age, and laboratory tests. Pre-endoscopic proton pump inhibitor (PPI) may be considered to decrease the need for endoscopic therapy but does not improve clinical outcomes. Upper endoscopy is generally performed within 24h. The endoscopic features of ulcers direct further management. Patients with active bleeding or non-bleeding visible vessels receive endoscopic therapy (e.g., bipolar electrocoagulation, heater probe, sclerosant, clips) and those with an adherent clot may receive endoscopic therapy.
Recommendations emphasize early risk stratification, by using validated prognostic scales, and early endoscopy (within 24 hours). Endoscopic hemostasis remains indicated for high-risk lesions, whereas data support attempts to dislodge clots with hemostatic, pharmacologic, or combination treatment of the underlying stigmata. Clips or thermocoagulation, alone or with epinephrine injection, are effective methods, epinephrine injection alone is not recommended. Ulcer bleeding is first treated by endoscopic hemostasis. If it fails, surgery or interventional radiology is chosen. Second, medical therapy is provided. In cases of NSAID-related ulcers, use of NSAIDs is stopped, and anti-ulcer therapy is provided. If NSAID use must continue, the ulcer is treated with a proton pump inhibitor (PPI) or prostaglandin analog. In cases with no NSAID use, 

\[ H. pylori \] positive patients receive eradication and anti-ulcer therapy. If first-line eradication therapy fails, second-line therapy is given. In cases of non- \[ H. pylori \]-positive patients, \[ H. pylori \]-positive patients with no indication for eradication therapy, non-eradication therapy is provided. The first choice is PPI therapy, and the second choice is histamine 2-receptor antagonist therapy. After initial therapy, maintenance therapy is provided to prevent ulcer relapse. [8,9,10]. In this case we treated the \[ H. pylori \] infection by giving triple drug consist of omeprazole 2 x 1 capsul, amoxicillin 2 x 1 gram and clarithromycin 2 x 500 mg for 14 days.

Prognosis of PUD is excellent if the underlying cause such as \[ H. pylori \] infection or drugs can be addressed. [11]. Prognosis of this case is dubius ad bonam. We plan to do esophagogastroduodenoscopy in the further next 3 months to reevaluate the treatment successfull.
