Abstract: When filler materials like carbon, graphite, glass fibres are added in the PTFE, a composite is formed which improves mechanical & thermal properties of that composite. It increases hardness and wear resistance, while the coefficient of friction is slightly affected and remains low. In this survey, we study various papers in which various methods & experiments were carried out for calculating friction & wear resistance of various compositions of polymers. So it is easy to understand properties & behaviour of polymers under various test conditions.

Keywords: Composites, PTFE, friction, wear

1. Introduction

Polytetrafluoroethylene (PTFE) is an important polymer based engineering material. When rubbed against a hard surface, PTFE exhibits a low coefficient of friction but a high rate of wear. It is white or gray in color. It is an ideal bearing material for heavy and light load pressures with medium and low surface speeds. The development of the fluoropolymer industry began with the discovery of the polytetrafluoroethylene (PTFE) by Dr. Roy J. Plunkett (1910-1994) at DuPont in 1938 and introduction as a commercial product in 1946. Polytetrafluoroethylene (PTFE) is a high performance engineering plastics which is widely used in industry due to its properties of self-lubrication, low friction coefficient, high temperature stability and chemically resistant. While PTFE exhibits poor wear and abrasion resistance, leading to early failure and leakage problem in the machine parts.

To minimize this problem, various suitable fillers added to PTFE. Generally, reinforcements such as glass fibres, carbon fibres and solid lubricants are added internally or incorporated into the PTFE. Its relative softness and poor heat conductivity limit its suitability as a bearing material to applications involving low speeds and low unit pressure, the tribological behaviour of polymers is affected by environmental and operating conditions and by the type, size, amount, shape and orientation of the fibres.

A relationship between the wear of the polymers and operating parameters is desirable to obtain the better understanding on the wear behaviour. In 1953, a new fluoropolymer, polychlorotrifluoroethylene (PCTFE) was commercialized by M. W. Kellog Company under the trade mark Kel-F. PCTFE is produced by the free radical polymerization of chlorotrifluoroethylene (CTFE) with a linear polymer chain structure.

Polytetrafluoroethylene (PTFE) polymer is a widely used solid lubricant. It is commonly used to provide a dry sliding friction coefficient $\mu < 0.2$ on a variety of counterface types including stainless steel. PTFE is a popular polymer solid lubricant because of its resistance to chemical attack in a wide variety of solvents and solutions, high melting point, low coefficient of friction, and biocompatibility.

It is commonly used in bearing and seals applications. Unfortunately, PTFE suffers from poor wear resistance. Gong et al. and Blanchet and Kennedy report unfilled wear rates of 7.36x10$^{-4}$ and 7.41x10$^{-4}$ mm$^3$/Nm, respectively. A hypothesis for the low friction of PTFE is that the long chains of PTFE, -(CF2-CF2)$n$-, orient on the transfer surface during sliding, forming a low shear-strength interface with the bulk PTFE bearing material. PTFE has a 13/1 or 15/1 helicalmolecular structure with the fluorine atoms close enough to form a smooth cylindrical surface against which other molecules can easily slide. Hard particulate fillers made of ceramic or metal particles, and fiber fillers made of glass have been used with a PTFE matrix to dramatically improve the wear resistance, even up to three orders of magnitude. The use of such hard particles increases the dry sliding friction coefficient and abrades the counterface. Counterface abrasion is not desirable in a solid lubricant bearing system. Novel non-abrasive PTFE systems with wear resistance similar to filled PTFE composites have been made using gamma and electron irradiation by Briscoe and Ni and Blanchet and Peng respectively. With the recent availability of nanoparticles it is hypothesized that composites made with such small fillers will be significantly less abrasive than their micrometer sized counterparts. Perhaps such composites will provide a new family of non-abrasive and wear-resistant solid lubricant bearing materials.

1.1 Test Conditions

- Load: Load is important factor when we consider friction & wear. As we know Friction & wear is directly proportional to the applied load.
- Velocity: When it’s deal with friction and wear testing machine, it is very necessary to consider the velocity of the specimen. Generally, frictional resistance decreases with increasing velocity.
Polymer composites filled by nano lowers the wear rate of the PTFE. with glass fibres improves the load carrying capability that mechanical properties. Therefore, the reinforcement PTFE is characterised by high wear because of its small composites decreases when applied under ambient conditions in a pin (GFR) and bronze and carbon (C) filled PTFE polymers polytetrafluoroethylene (PTFE), glass fibre reinforced (GFR) and bronze and carbon (C) filled PTFE polymers under ambient conditions. The friction coefficient of pure PTFE and its composites decreases when applied under ambient conditions in a pin-on-disc arrangement. It was found that the load carrying capacity of the SFRPs is mainly determined by the properties of the fibers. However, the tribological performance of SFRPs can be significantly improved by using nanoparticles due to their friction reducing abilities, especially under extreme loading conditions.

3. Methodology

Various test methods are available for friction & wear testing. Some of them are explained below,

- The influence of test speed and load values on the friction and wear behaviour of pure polytetrafluoroethylene (PTFE), glass fibre reinforced (GFR) and bronze and carbon (C) filled PTFE polymers under ambient conditions in a reciprocating motion piston arrangement.

[1] H. unal et al (2004) “Sliding friction and wear behaviour of polytetrafluoroethylene and its composites under dry conditions” in Materials and Design 25 (2004) 239–245 presented the influence of test speed and load values on the friction and wear behaviour of pure polytetrafluoroethylene (PTFE), glass fibre reinforced (GFR) and bronze and carbon (C) filled PTFE polymers under ambient conditions in a pin-on-disc arrangement concluded that The friction coefficient of pure PTFE and its composites decreases when applied load increases also pure PTFE is characterised by high wear because of its small mechanical properties. Therefore, the reinforcement PTFE with glass fibres improves the load carrying capability that lowers the wear rate of the PTFE.

[2] Ayman A. Aly, et al (2012) “Friction and Wear of Polymer Composites Filled by Nano-Particles: A Review”, World Journal of Nano Science and Engineering, 2012, 2, 32-39 has reviewed about friction & wear effects on nano particles filled composites. The survey showed that there is a significant improvement in mechanical properties of the composite due to the addition of the nanoparticles. Many types of nanofilling martials, including SiC, Si3N4, SiO2, ZrO2, ZnO, CaCO3, Al2O3, TiO2, and nano-CuO, have been used to different types of polymers such as PEEK, PMMA, PTFE and epoxy. The mechanical properties which have been improved include fatigue resistance, fracture toughness, tensile strength, wear resistance, and friction coefficient.

[4] Li Chang et al (2010)“Enhancement effect of nanoparticles on the sliding wear of short fiberreinforced polymer composites: A critical discussion of wear mechanisms” Tribology International 43 (2010) 2355–2364 investigated the wear mechanisms of the hybrid SFRPs filled with nano particles on pin on disc arrangement. It was found that the load carrying capacity of the SFRPs is mainly determined by the properties of the fibers. However, the tribological performance of SFRPs can be significantly improved by using nanoparticles due to their friction reducing abilities, especially under extreme loading conditions.

- Create a 3D Model of the wear test setup using catia software.
- Create a 3d model of piston which is of PTFE composite.
- In these experiments we carried out the friction and wear tests on a reciprocating motion piston with the help of cam n follower.
- To perform friction n wear analysis is Ansys.
- Based on results design changes are implemented to reduced friction.
- To calculate wear analysis of the shaft which is made up of PTFE composite.
- Testing of wear and friction of PTFE composite material.

Frictional contact is defined between piston and cylinder with coefficient of friction is 0.2

This is Von-Mises stress plot. As expected the stress decreased after the volume wear out

5. Conclusion

From the overview of above study concludes that,
1) Addition of filler materials such as bronze and carbon to PTFE causes an increase in wear resistance, while the coefficient of friction is slightly affected.
2) The friction coefficient of pure PTFE and its composites decreases by increasing applied load, which can be improved by reinforcement PTFE with glass fibres.
3) For the specific range of load and speed, the load has stronger effect on the wear behaviour of PTFE and its composites than the reciprocating velocity.
4) Addition of filler materials such as carbon, graphite, glass fibers and PPDT to PTFE causes an increase in hardness and wear resistance, while the coefficient of friction is slightly affected and remains low. Filler materials in general are effective in impeding large-scale fragmentation of PTFE, thereby reducing the wear rate.
