Abstract: SBS are the expected approach in achieving 5G targets. Indeed, reducing cell sizes through the use of heterogeneous networks (HetNets), employing greater spectral efficiency at each BS and, an increase an in spectrum are seen as solutions to meet the requirements of future wireless networks. These fall under the category of “network densification”, provided by spatial densification and spectral aggregation. Spatial densification is achieved by increasing the number of antennas at the SBS and increasing the density of SBSs per m². Antennas requirements will be crucial in spatial densification in achieving 5G requirements.

Keywords: SBS, 5G, Antenna types

1. Introduction

The recent advancement of wireless networks have seen a change from traditional macro cell base stations (MBSs) covering a wide areas e.g. 10s of kilometres, to the introduction of much smaller footprint small cell base stations (SBSs). These typically include pico-cells, femto cells, and ultra-dense small cells covering 100s to 10s of meters. Furthermore, it is widely agreed that increasing the number of cells with small radii will be the main contributor of the next generation cellular system (i.e. 5G) to increase the network capacity and to provide required data rates. Hence, SBS are the expected approach in achieving 5G targets. Indeed, reducing cell sizes through the use of heterogeneous networks (HetNets), employing greater spectral efficiency at each BS and, an increase in spectrum are seen as solutions to meet the requirements of future wireless networks [1], [2]. These fall under the category of “network densification”, provided by spatial densification and spectral aggregation [2]. Spatial densification is achieved by increasing the number of antennas at the SBS and increasing the density of SBSs per m².

The paper is organized as follows - Section 2 discusses various antenna types used in small base station, Section III provides a discussion into recent research surrounding the use of multiple antennas in current generation SBSs to overcome interference problems in HetNets.

2. Antenna types used in SBS

2.1 Small Antenna types:

In first generation SBSs, the antenna system is of a static nature. Usually such installations use simple dipole or printed circuit board antennas (PCB-antenna) with low gain and rather omni-directional, fixed patterns commonly termed as small antenna types [3]. The most popular and efficient small antenna types:

¾ Wave Whip (Monopole)

A whip antenna provides exceptional overall performance and stability, has an isotropic pattern, a wide bandwidth, it is cheap and it is easily designed. Since a full-wave or even a half-wave dipole whip is generally quite long, most whips are ¾ wave. Note: If one branch of the dipole antenna is replaced by an infinitely (enough) large ground plane, due to the effect of mirroring, the radiation pattern above the ground plane remains unaffected and delivers practically quite the same performance of a whole half-wave dipole. This simple and most effective small antenna is also called a quarter-wave monopole and is the most common antenna on today’s portable devices. Since most devices have a circuit board anyway, using it for half of the antenna can make a lot of sense. Generally, this half of the antenna will be connected to ground and the transmitter or receiver will reference it accordingly.

Helical

A helical element is a wire coil usually wound from copper, brass, steel or can be even realized on PCB. Compared to the monopole, which is essentially a two-dimensional structure, the helical antenna is a 3-dimensional structure but is nothing else as a “shorter quarter wave”. Its radiation pattern is similar in nature to the monopole. This provides an optimum condition for portable communications. A small helical significantly reduces the needed physical size of the antenna and that is important at lower frequency (larger antennas); however this reduction is not without a price. Because a helical has a higher Q factor, its bandwidth is narrower and its ideal gain is as a matter of principle lower than a “full size” quarter-wave whip. In many cases, the helical antenna will perform as well as the elongated ¾ wave antenna. The distributed capacity of the helical ¾ wave antenna acts as an impedance matching section that is not present in the full size ¾ wave antenna and minimizes the effect of the underground.

PCB antenna

PCB antenna is nothing else as a “special ¾ wave whip” antenna where the whip is realized as copper trace on a PCB board. A PCB antenna is stable, reproducible, easy to manufacture and uses the existing board.

2.2 Dipole types

The dipole antenna consists of two conductive elements such as metal wires or rods which are fed by a signal source or feed energy that has been picked up to a receiver[24]. The energy may be transferred to and from the dipole antenna either directly straight into the electronic instrument, or it may be transferred some distance using a feeder. This leaves considerable room for a variety of different antenna formats.

Although the dipole antenna is often though in its half wave format, there are nevertheless many forms of the antenna that can be used.

**Half wave dipole antenna**: The half wave dipole antenna is the one that is most widely used. Being half a wavelength long it is a resonant antenna.

**Multiple half waves dipole antenna**: It is possible to utilize a dipole antenna or aerial that is an odd multiple of half wavelengths long.

**Folded dipole antenna**: As the name implies this form of the dipole aerial or dipole antenna is folded back on itself. While still retaining the length between the ends of half a wavelength, an additional length of conductor effectively connects the ends together. Read more about the Folded-dipole.

**Short dipole**: A short dipole antenna is one where the length is much shorter than that of half a wavelength. Where a dipole antenna is shorter than half a wavelength, the feed impedance starts to rise and its response is less dependent upon frequency changes. Its length also becomes smaller and this has many advantages. It is found that the current profile of the antenna approximately a triangular distribution. Read more about the Short-dipole.

**Non-resonant dipole**: A dipole antenna may be operated away from its resonant frequency and fed with a high impedance feeder. This enables it to operate over a much wider bandwidth.

2.3 Microstrip patch antenna

The use of multiple antennas in SBSs face several challenges such as complexity, increased signal processing, cost and physical limitations associated with the form factor of small cell housings [8], [9]. Microstrip patch antennas are generally chosen as the technology for diversity antennas for both mobile BSs and terminals because of its advantages of compactness and easy fabrication [12], [13]. Patch antennas are a form of microstrip antenna based upon printed circuit board (PCB) technology to create _at radiating structures on top of dielectric, ground plane backed structures [14]. These have suitability for SBSs because of their low cost and high reliability. Microstrip patch antennas are widely used in the microwave frequency region because of their simplicity and compatibility with printed-circuit technology, making them easy to manufacture either as stand-alone elements or as elements of arrays. The advantages of microstrip antennas make them suitable for various applications like, vehicle based satellite link antennas [2], global positioning systems (GPS) [22], radar for missiles and telemetry [21] and mobile handheld radios or communication devices [3]. In its simplest form a microstrip patch antenna consists of a patch of metal, generally rectangular or circular (though other shapes are sometimes used) on top of a grounded substrate [23].
2.4 Planar inverted – F antenna

The use of planar inverted-F (PIFA) antennas are another form of microstrip antenna which are popular in mobile phone/UE technology because they are resonant at 1/4 \( \lambda \) [15], where \( \lambda \) is the wavelength corresponding to the frequency of operation. They are therefore attractive in terms of their physical properties, which makes them equally suitable for SBSs.

![Figure 3: Typical PIFA antenna](image)

2.5 E-plane horn antenna

The use of E-plane horn antennas, a physically flared (in the direction of the electric E field) antenna which is a natural evolution of the idea that any antenna represents a region of transition between guided and propagating waves [14], have also found use in SBSs applications [16]. E-plane horns offer moderate directivity and since they do not have any resonant elements they can operate over a wide range of frequencies.
