The Prevalence of Parasitic Infection of Entamoebahistolytica, Giardia lambilia and Enterobiusvermicularis in Kilowa Governorate, Saudia Arbia

Mohey El-Din Z. Abd El-Latif

Zoology Department, Faculty of Science, South Valley University – Qena, Egypt

Abstract: This study aims to study the prevalence of Entamoebahistolytica, Giardia lambilia and Enterobiusvermicularis infections in Kilowa Governorate, Saudia Arbia, by using the microscopic methods. The study was conducted on the (78) stool samples from diarrhea-suffering patients. Patients ages ranged from 1 to 15 years old and from both sexes to estimate the prevalence of some intestinal parasitic diseases in the general population using the data of laboratory of general hospital at Kilowa Governorate, by using the microscopic methods to distinguish between Entamoebahistolytica, Giardia lambilia and Enterobiusvermicularis infections. The most common parasite was Enterobiusvermicularis (9%) and Entamoebahistolytica wascasua (6.4%), while the infection by Giardia lambilia was 0 patient.

1. Introduction

Intestinal parasites are parasitic primordial organisms that live in the human intestines and feed on digested food and blood and cause serious diseases that affect health greatly. The most important of these parasites are Entamoebahistolytica, Enterobiusvermicularis and Giardia lambilia. Intestinal parasitic infection is a major health problem in many developing countries by increasing standards of health and controlling the carriers or intermediate hosts, most industrialized countries have successfully decreased the rates of infestation. In developing countries, however, geographic and socioeconomic factors as well as unpredictable factors such as natural disasters contribute to the problem. These countries are mainly located in warm or hot and relatively humid areas that, combined with poverty, malnutrition, high population density, unavailability of potable water and low health status, provide optimum conditions for the growth and transmission of intestinal parasites. The prevalence of infections varies in different parts of the world. The prevalence of Entamoebahistolytica, for example, ranges from 5% to 81% and is estimated to involve around 480 million people worldwide. Giardia lambilia is the most common intestinal parasite in the United States. Of the 3% to 7% of the population with G. lambilia in Australia, 1.6% were asymptomatic. In a study in China, Enterobiusvermicularis (47.0%), Trichuristrichiria (18.8%) and Taenia saginata (17.2%) were the most frequent causes of intestinal parasitic infections. Studies have shown that the prevalence of intestinal parasitic infection is higher in younger people, especially children [5]. For example, an extensive survey in Malaysia reported the overall prevalence of intestinal parasitic infections as 39.6% with as many as 89.0% in children between the ages of 2 and 12 years. Geographical conditions and poor nutritional and socioeconomic status contribute for making the Islamic Republic of Iran a favourable area for parasitic infections. A review of 300 cases of intestinal parasitic infection showed that A. lumbricoides was the most common nematode and G. lambilia and E. histolytica the most common unicellular microorganisms causing intestinal parasitic infections (A.A. Sayyari, et al. 2005).

Seven species of protozoan were found in the fecal samples, indicating the contamination of drinking water and poor hygiene among the children in Thailand. The most common species was Entamoeba coli (25.8%) a non-pathogenic protozoal. Other non-pathogenic species, listed according to their frequency of occurrence, were: Endolimax nana (2.5%), Chilomastixmesnili (0.3%) and Iodamoebabutschlii (0.1%). Three pathogenic species were found: Giardia lambilia (5.3%), Entamoebahistolytica (1.4%), and Blastocystishominis (0.8%), all of which may cause diarrhea; moreover E. histolytica can invade organs and cause amebic abscesses in the liver and brain [J Waikagul et al. (2002)].

A study on the prevalence of parasites among the patients in Qina Province, Egypt. It showed that the infection of the parasite Entamoebahistolytica in 135 patients in the rate of 90% and the parasite Girdialambilia affected 60 of the patients in the rate of 40%. Mohey El-Din Z. Abd El-Latif, (2019).

Different intestinal parasites, whether intestinal protozoa, such as Entamoebahistolytica and Giardia lambilia, or Ascarissp. or Taenia sp. are considered the most widespread parasites on the world level in general and in the third world in particular, as their spread is not related to the Vector hosts, Environmental conditions such as high temperature and excess humidity, in addition to poor economic and social conditions such as poverty, lack of clean water supply and low level of health services increase the prevalence of intestinal parasites and reduce the chances of controlling them or eliminate diseases that cause (Dienget al., 1999).

According to the World Health Organization (WHO), the incidence of amoebic dysentery varies from 5% of the population in developed industrialized countries to areas
with good health conditions, reaching more than 60%, especially in children in some tropical regions and poor countries with severe in clean water and apparent lack of health services (Dienne et al., 1999). The total number of patients with amoebic dysentery is about half a billion people in the world concentrated in the Third World (Thompson, et al., 1990 & 2001).

Several studies have shown that most people with intestinal parasites are children or Adults, a study in Malaysia showed that intestinal parasites were present in at least 39% of patients aged from 2 to 12 years, accounting for 89% of the patients (Leroy et al., 1998).

Intestinal parasites affect approximately 3.5 billion people worldwide and are a public health problem, especially in developing countries, where almost one-third of the population live in conditions favorable to their dissemination. Amebiasis is the second most frequent parasitic disease, causing around 100,000 deaths each year and contributing toward the high global burden of diarrhea, notably in regions with low economic development and settings with poor sanitation (Juliana de Oliveira Costa et al., 2018).

*Enterobius vermicularis* has a worldwide distribution and is one of the most common parasitic helmint infections in the developed world (Cook and Zuma, 2003). It is estimated that 400 million people are infected with diphtheria all over the world (Stephan et al. 2006). Appendicitis is the most common acute surgical condition for the abdominal emergency in the Western world, which occurs in 7-12% of the general population (Baert, 1999).

In Nepal, a total of 624 diagnosed cases were identified (1.62%) of patients with clinical diagnosis of appendicitis. *Entamoeba vermicularis* was often found in non-flammable and histologically normal supplements (8.45%) of those that were inflamed with histopathological changes of acute appendicitis (0.56%) (Sah and Bhadani, 2006).

Another study was conducted in Iran involving 5048 samples. *E. vermicularis* was found in 144 patients (2.9%) of appendicitis patients (Ramezani and Dehghani, 2007).

In the UK, an evaluation of histological materials obtained from all accessories removed during the past 5 years was carried out at Bristol’s Southamid Hospital. *E. vermicularis* was identified in 2.7% of patients with clinical appendicitis (Pod and Armstrong (1987). The simple presence of *E. vermicularis* in the bowel often results in symptoms similar to acute appendicitis, although the mechanism does not include mucus invasion by the parasite (Sah and Bhadani, 2006). While Gutiérrez, (2000) asserts that there is consensus that pinworms do not produce inflammatory response. Burckhart, (2005) mentioned that the infection of pinworm causes the symptoms of appendicitis on the surface.

The prevalence of intestinal parasites was determined for 78 patients in Kilowa Province. During the period from the first of March to the 20th of April 2019, in age ranging from 1 to 15 years old. For fecal samples, microscopy was used to identify the presence of parasites and buoyancy techniques. Two types of intestinal parasites were detected during this study.

### 2. Materials and Methods

78 clinical samples were collected from patients in the laboratory of general hospital at Kilowa Governorate, Saudia Arabia.

- These samples have been examined softened by a hyeno-electric microscope.
- This worms were isolated by using float method and adhesive tape, then loaded onto glass slides and covered with Canada Balsam and dried in the oven.
- The worms samples were photographed by using a camera.

### 3. Results

Table (2) shows the relationship between the age of the patients in the study and the prevalence and percentage of infection of the parasite *Entamoeba histolytica*, where it shows that the number of infection in this parasite at the age less than 10 years 3 cases, with percentage 3.8 %. At the age of 10 to 15 years, the incidence was 2, with percentage 2.6 %.

Table (2) shows the relationship between the age of the studied patients and the prevalence rate and percentage of the infection of the parasite *Giardia lambilia*, where the number of infection with this parasite was zero with percentage 0.0 %.

Table (2) shows the relationship between the age of the patients and the prevalence and percentage of infection of the parasite *Enterobius vermicularis*, where it shows that the number of infection in this parasite at the age less than 10 years 5 cases, with percentage 6.4 %, while at the age of 10 to 15 years, the incidence was 2, with percentage 2.6 %.

4. Discussion

This study shows that intestinal parasitic infections are one of the most important health problems facing the population in Kilowa Province, Saudi Arabia. The findings of studies performed in other countries such as Brazil, China, Egypt and Pakistan are comparable to the results of this study. In 1983, in the United States of America, *G. lamblia* was identified as the cause of 68% of waterborne outbreaks of diarrhoea in which an etiologic agent was unknown. We found that intestinal parasitic infections are more common in rural than urban areas. People living in rural areas may lack sanitary water supplies and live close to sources of parasites in social and environmental conditions that predispose to intestinal parasitic infections. According to this study, the common intestinal parasitic infections were more frequent in children, which suggests that screening tests for this age group may be useful. Because the prevalence of parasitic infections is high in developing countries, it is suggested that local or regional researchers undertake studies on such infections in these countries, perhaps with the technical support of the World Health Organization.

The results of the current study show that the incidence of infection varies from one parasite to another and that the most common disease among the patients is the parasite *Enterobius vermicularis*, where the incidence of about 9% compared with *Entamoebahistolytica* parasite, where the rate of infection was about 6.4%. These results are higher than the results obtained by (Rayanet al., 2010) in their study of intestinal parasites in Australia (4.2%) for the group of children ages 5 to 11 years. (Al-Harthe et al., 2004) in their study of the prevalence of intestinal parasites among school children between the ages of 7 to 12 years in Mecca, Saudi Arabia, where the percentage of infection with *Entamoebahistolytica* 1.01%, and this study differs from the results of (Al-Fahdawy, 2007) where he confirmed that the most common parasites is *Entamoebahistolytica* by 26.4%.

These results are lesser than that obtained by (Moheyeldeen Z. Abdellatif, 2019) in his study on intestinal parasites *Entamoebahistolytica and Giardia lamblia*in Qina, Egypt (90 % and 40 %) respectively, for the group of patients aged from1 to more than50 years. (Al-Harthe et al., 2004) in their study of the prevalence of intestinal parasites among school children between the ages of 7 to 12 years in. The cause of the spread of parasitic infection is transmitted directly through contaminated food and water, as well as lack of attention to personal hygiene and the spread of pollutants in food and drinking water. The infection rate was 61.21% and higher than recorded by (Al-Issa et al., 1986), where the infection rate was 21.5%.

The study showed that the highest incidence of *Entamoebahistolytica* and *Enterobiusvermicularis* were in the patients less than 10 years, i.e., children and school students, due to the lack of health awareness and lack of understanding of the risk of such parasites and the possibility of transmission of infection between Children and schoolchildren during play and low immunity. This study showed a decrease in the prevalence of parasitic infection in the community of Kilowa, Saudi Arabia compared to other developing countries due to the presence of comprehensive health care and treatment and medicine free of charge for all members of the community and the existence of periodic health follow-up on schoolchildren in all stages and the existence of an excellent sewage network in Maintain and maintain permanent control over the sources of drinking water and food
