Abstract: *Sacred Groves are the tracts of virgin forests; the vestiges of an ancient practice in which people has been protecting forest patches associated with home, temple, agricultural fields or in public places to avoid the perceived wrath of its resident God. In such groves all life forms including microbes are belong to deity and it is believed that, any harm to them invites the displeasure of deity in the form of disease or decease. These terrestrial forest ecosystems are usually in association with fresh water conservatory and this together extent a number of ecological, edaphological and conservational services in the landscape of Kerala. In Kerala the natural forests are extended in the high ranges and highland area (Altitude above 100 m MSL), the sacred groves are distributed in midland or lowland regions (Altitude below 100 m MSL) where the natural forests are not seen. The sacred groves have a comprehensive environmental role in the track of urbanized landscape ecology of the state by protecting flora and fauna. The investigation divulges the unparallel and unique floristic accounts, distinct ecological and conservational values of vegetation, which are extended to the traditional landscape of the state which are succumbed to various anthropogenic pressures.*

Keywords: Conservation, Floristic Wealth and Diversity, Sacred Grove of Kerala, Traditional Landscape

1. Introduction

Traditionally managed Sacred Groves of Kerala (SGK) locally called *Kavu* can be considered as the typical example of Indian ethos for *in situ* conservation and protection of local environment and biodiversity in the socio-religious ground. This traditional worship place and associated practices show the organized organic relation between human and nature, the indigenous people of Kerala lived in accordance with the nature's rule and conserved local bio-treasure in its original habitat. In advancement of civilization, science, technology, industries which spreadout and established the urbanization. The socio-political scenario of state undergoes changes along with the expanded requirement of the basic lifestyle of the people. The associated anthropogenic activities have altered the traditional landscape of state, also sacred groves, which affect the existence of these relic patches of vegetation by and large. The existing grove ecosystems still have been providing many environmental and conservational services including watershed value, biological control, chest of wild genetic resources and with a multidimensional array of social, cultural, religious, and aesthetic values. In the midst of urbanization SGK is protecting indigenous lifeforms in association with the abiotic factors without any external stress, due to the religious and social restrictions. Hence, one of the most conspicuous effects of these ecosystems perturbation is the depletion of biodiversity and habitat losses which initially result in the disappearance of native species due to habitat alteration followed by invasion of exotic species and finally total ecological and edaphic discrepancy. The floristic elements are mostly evergreen and hygrophilous in nature with the resemblance of evergreen forest of Western Ghats. The trees are in three indistinct layers with 50-30 meter height and are rich with woody lianas, parasites and epiphytes. The undergrowth largely consists of herbaceous or woody erect plants including geophytes, saplings and seedlings of trees, shrubs and lianas. A portion of ground vegetation is represented by elements of

angiosperms, pteridophytes, bryophytes, and fruiting bodies of fungi. The sacred grove's flora, relic vegetation of Western Ghats, is being considered as the "climatic climax" in the state of equilibrium. The vegetation is tropical and phanero-therophytic with high structural resemblance to the forests of the Western Ghats, mostly with evergreen, semi-evergreen and moist deciduous types and rarely freshwater swamp and mangroves. The floristic diversity indices like Simpson's index and Shannon Weinner's index are equal or almost equal to the Western Ghats' flora. The phytosociological data and other salient features are also equated with Western Ghats's vegetation. The values of species richness and tree density also indicate affinity of SGK to Western Ghats. The biological spectrum of SGK is similar to normal spectra of evergreen forests of the world as well as forests of Western Ghats, also supporting the above arguments and in fact, SGK are not only possessing common floristic elements along with species nova but also on the abode of many endemic, rare and threatened plants of conservational significance. The present investigation and analysis have been carriedout based on the exploration trips and field studies conducted in 200 bio-geographically divergent sacred groves categorized into five sites. The exploration results that the SGK are rich in floristic diversity with different array of life forms which are disappearing from other areas due to the developmental activities. Additionally, SGK also have species nova, RET and other eco-economically important genetic resoruces. But now a day groves, are totally susceptible from all type of disturbances due to the erosion of traditional, socio-religious restrictions and developmental activities. This vegetation is nothing but the relic of old vegetation which has been extended in Kerala before civilization is largely being disappearing.

2. Literary Survey

Sacred groves are distributed across the globe and conserve ethnic ethos and natural landscapes keeping the virgin forest

and its bio-wealth. These groves are also widely distributed in all bio-geographical regions of India [1]. The study about sacred groves of India started in 1903 by Gammie in the form of inventory [2]. Then it was extended to various parts of the country by many scientists namely Bor, Raja, Gadgil and Vartak and Vartak and Gadgil [3], [4], [5], [6], [7]. The scientific accounting and evaluation of sacred groves of Western Ghats was initiated with Gadgil and Vartak [8] from Maharashtra state. Gadgil and Mehor-homji [9] attributed the traditional practices by most indigenous communities of necessary protection of natural ecosystems by setting aside of these refugee in socio-religious ground. Chandran and Gadgil [10] and Chandran [11] elaborated various biological, religious, historical, economic and ecological aspects of the sacred groves. In 1998, Chandran *et al* [12] had inventorized the role of this abode of Gods, would have who protected a range of landscape elements with their characteristic biodiversity. In Kerala, the study on *Kavu* is gained impetus with pioneering work of Mohanan and Nair [13] through floristic inventory. The authors were collected new species *Kunstleria keralensis* and rediscovered *Syzygium travancoricum* after the discovery of Bourdillon in 1894 [14]. A tree species *Madhuca diplostemon* also relocated after a long period of 180 years, believed to be extinct, from a grove of Kerala [15]. In 2014, a new species of *Cinnamomum* namely *C. mohananii* has described from SGK by Jagadeesan *et al* [16]. New species, *Biophytum veldkampii* and *Grewia palodensis* were described from SGK by scientists of JNTBGRI [17], [18]. These all designate the SGK are sanctum sanctorum of flora which are extinct in other ecosystems, including natural forests. Rajendraprasad [19] had documented uniqueness of floristic ecology of selected sacred groves of Kerala along with description of bio-wealth, biodiversity, general ecology and physical edaphology. Balasubrahmanyam and Induchoodan [20] documented the floristic account of 761 selected sacred groves of Kerala. The notable study on ecology and edaphology on groves and its associated aquatic ecosystem shows that it always operates water shed area at local level by minimize the surface runoff and enhancing the infiltrate rate [19], [21].

3. Study Sites

In India, the state Kerala constitutes a natural geographic unit, rising as it were, from Arabian Sea to Western Ghats. The south west corner peninsular state extended from $08^{\circ}2'$ to $12^{\circ}8'$ N. Latitude and $74^{\circ}8'$ $77^{\circ}5'$ E. longitude, covering an area of 38864 square kilometers. Phyto-geographically Kerala is divided into three natural physical divisions, the westernmost coastal plain adjoining to Arabian Sea is picturesque lowland, and altitude is > 20 meter below MSL. On moving inland, there is a progressive elevation of topography with rising lateritic hills, undulating clusters of hills and valleys representing midlands, altitude is in between 20 and 100 meter above MSL. Again moving to east the elevation abruptly increase is marking the beginning of the large mountains with rivers in its origin, waterfalls, and virgin tropical vegetation distributed above 100 meter above MSL representing the highlands. The climate of Kerala is tropical, warm humid and monsoonal with annual rainfall of above 2500 mm with rains for nearly 8 to 10 months. The

temperature and humidity are moderate throughout the year [Fig1. (a) and (b)].

4. Materials and Methods

i) Data Collection

The botanical survey and inventory was conducted in 200 randomly selected sacred groves covering all phyto-geographical divergent areas (notified as five sites). All species present in each sampled sacred groves were identified and recorded by botanical name and that was latter confirmed from Jawaharlal Nehru Tropical Botanic Garden and Research Institute Herbarium (TBGT). The meteorological data of each site was obtained through government sources located fairly close to study site.

ii) Data Analysis:

The collected species were categorized on family basis and geographical distribution and status were recorded. The habit of each individual based on the morphology and position of apical bud of fully grown member was assessed for the construction of the biological spectrum [22], [23]. The percentage of species belonging to each life forms class was determined by the formula

$$\% \text{ of life form} = \frac{\text{No. of species of any lifeform}}{\text{Total no.of species of all lifeforms}} \times 100$$

The abundance (number of individuals per species), frequency (fraction of sacred grove contains the species), dominance (occupying status) were calculated. The important Value Index (IVI) were calculated by summing up the average relative frequency (rf), relative density (rd) and relative dominance (rD) following Misra & Puri [24]; Misra [25]; Dombois & Ellenberg [26]; Curtis & Mc Intosh [27]; Curtis [28]; Pascal [29].

The floristic similarities between groves of different study sites were calculated using the formula, Dombois & Ellenberg [26].

$$\text{Similarity Index} = \frac{\text{Number of common species}}{\text{Total number of species}} \times 100$$

The distribution pattern and conservation status of each species computed as follow

$$\text{Whiteford Index} = \frac{\text{Abundance}}{\text{Frequency}}$$

$$\text{Abundance} = \frac{\text{Total no.of individual of 'i' species}}{\text{No.of Quadrat in which it occur}}$$

$$\text{Frequency} = \frac{\text{No. of Quadrat with 'i' species}}{\text{No.of Quadrat studied}}$$

The index value of 0.025 to 0.050 indicates that the species is random, while value higher than 0.05 indicates increase in aggregation and values lower than 0.025 shows the tendency towards regularity [30].

The floristic diversity was calculated with following indices:

$$\text{Simpson Index (D)} = 1 - \sum (n_i / N)^2 [31]$$

$$\text{Shannon Wiener's Index (H')} = - \sum [n_i / N] \log_2 [n_i / N]$$

$$H_{(\max)} = \log_2 S$$

$$\text{Equitability (E)} = H' / H_{(\max)} [32]$$

Where,

n_i = Number of individual of the i^{th} species

N = Total number of individuals

S = Number of species.

5. Results and Discussion

The Sacred Groves of Kerala (SGK) are the traditional forms of conservatory, the religious places that has biological, ecological, social, cultural, and religious significance. The area of individual grove varies from a few square meter to many square kilometers and usually it may be attached to temples or traditional heritage homes (locally called *Tharavadu*) as a subsidiary worship place, and are sometime with independently in association with cultivated lands or isolated lands in form of main worship place. This protected virgin forest is immune from all type external disturbances due to religious restriction or social taboos; hence it is possible to conserve wide flora and fauna keeping equilibrium with adjacent ecosystems. The one and most important ecological and conservational functioning of SGK is protection and conservation of biodiversity which are disappearing from other areas of Kerala and creation of positive water regime. The SGK are approved with remarkable occurrence of floristic wealth and diversity including *species nova* and relic vegetation being considered as Sanctum Sanctorum of ancient extended vegetation [Fig. 3 & Fig.4]. Phyto-sociological values and structural data also signify the importance of conservation values. The vegetation is characterized by luxurious growth of different array of flora, which consists of three different tiers, in which the highest often attains a height of 30 to 50 meters, according to the architecture of emergent and keystone species of each grove. Some of the members are buttressed at the base and boles are cylindrical which is branched from two thirds of the height with spreading or umbrella shaped crown at the top. The middle stratum is more or less candle shaped and lower characteristically conical in appearance. The trees are sheltered with several epiphytes such as orchids, arams, pteridophytes, and lichens. The dead or diseased individuals are normally occupied by different types of polyporales and other saprophytes. Trees with smooth barks are common while fissured bark and cauliflory or ramiflory are occasionally noticed. The presence of these wide spectrums of life forms with mutual interaction possesses a biological equilibrium status - the 'Climatic Climax' to the SGK.

The species richness in SGK has ranged from 26 to 55, designate that each and every groves are islands of diverse plants and contribute a key role in biodiversity conservation of Kerala. A total of about 326 angiosperm species belonging to 247 genera and 86 families were identified as core species and 407 species as associates. The dominant families were Rubiaceae, Fabaceae, Asteraceae, Orchidaceae and Lamiaceae. Among the 247 genera 64.60% is rare in occurrence and distribution, 19.60% seldom present and 09.30% is often present in SGK. Among the other group only 05.20% is common and 01.30% is very common in distribution. Regarding the distribution pattern of the species, most of them are distributed in patches, or in clumped aggregation, especially in a very local distance scale. It is of some interest that species which are highly aggregated

nevertheless are still present in low numbers, as rare species elsewhere in the grove, there is a random mixing of tree species and almost all of them appear to be having their own individualistic dispersion pattern and are uneven or clumped occurrence. The SGK in undisturbed condition have the girth distribution pattern of 'L' shape indicating sustainable self generating nature. The floristic diversity index, Simpson's index (D) in the different SGK at different sites varies from 0.8617 to 0.3719. Similarly, Shannon's Weiner's (H') also shows a range of 2.23 to 3.80. Within the same sacred grove we can observe the different magnitude of diversity indices [Table.1]. The earlier works in sacred groves of states along the Western Ghats are also supporting the present investigation [6], [7], [8], [33], [34]. The similar types of studies conducted by different authors also envisage the role of sacred groves in conserving biodiversity and keeping the ecological balance of the local regions. Some of earlier studies also acceptably point out the importance of sacred groves in conserving the flora and fauna by protecting the ecological conditions of landscape of Kerala state [19], [21], [35]. The element of floristic similarity between different sacred groves of phyto-climatically divergent regions shows that a minimum of 32.00% and a maximum of 68.06%. The minimum was noted between site number 1 and site number 3, groves of coastal - central regions and highland - central regions of the state. The maximum similarity is observed in between S2 and S3, the sites representing central midland and central highland. The variation in the south-north direction is moderate and even. The results indicate that there is a positive co-relation between distribution of flora and to its agro-climatic region. The variation between highland and coastal flora is highest in analysis, with minimum similarity index. The floristic similarity between highland and midland was highest, and of coastal and midland is moderate. This clearly indicates that flora of the state is in a continuous way with longitudinal base [Table.2]. The main criteria for the floristic variation are nothing but topography rather than agro climatic conditions. In addition to this floristic richness, faunal diversity is very significant with representation of vertebrates like mammals, birds, reptiles, amphibians, fishes and non-vertebrates by arthropods, mollusks, insects etc. The structural features may indirectly support the very wealthy distribution of other fauna also. Further that rare, endangered, threatened and endemic species are highly concentrated in these groves highlighting the conservational status of these centuries old traditional way of *in situ* conservation.

There is a wide variation in the floristic composition, structure and vegetational dynamism. The number of species varies from 26 to 216. The vegetation is predominated with tree species. The tallest tree reaches to over 60 meters and always a stratified structure is recognizable. The highest storey consists of a relatively small number of giant with openings in canopy. The discontinuous is always well above the denser middle and lower strata. The vegetation is evergreen and hygrophilous since the climate is warm and moist throughout the year and there is no seasonally limited growing. The individual trees shed their leaves seasonally or extending throughout the year. Litter formation and decomposition are in rapid manner utilizing conducive microclimate and soil conditions. The faunal activities including the microbial decomposition also accelerate the

processes of mineralization. Hence the soil becomes acidic and nutrient rich for supporting plant wealth and diversity. SGK also provide ecosystem services like controlling local climate, progressive water regime by maintaining water table, as a buffer for agricultural land from desertification by accelerating nutrient recycling and preventing soil erosion. These ecosystems also maintained the consistency of local food web and regulating the biological control of harmful pest and made way to cross pollination.

The sacred groves are protected around the world for a variety of reasons with different cultural dimensions such as religious or social practices with some rituals [36], [37], [38], [39], [40]. In Kerala, sacred groves are also functioning according to the traditional ecological, social cultural/religious background [19]. In India the sacred groves are distributed North West states to North East and states along the Western Ghats. It is also common in central India with high density sates along the Western Ghats. Recently the villagers of Kumaon Himalayas realized that Gods were the best guards for their forest, so they have declared their forest as sacred in order to protect them from destruction [41]. In Tamil Nadu the sacred groves are an important traditional method of both *in situ* and *ex situ* conservation of ecologically, economically and spiritually valuable tree species (MSSRF, 1997).

The SGK has provided many ecological and environmental services along with a multidimensional array of social, cultural, religious, aesthetic and conservational values. Once largely forested Kerala are now the forest distribution is

delimited and restricted to highland regions only. Paradoxically the sacred groves are mainly distributed in lowland and midland regions of Kerala have succumb to conservational existence due to lack of natural forest. All these factors indicate that the conservation of sacred groves attained the utmost importance in Kerala for maintaining traditional ecological equilibrium in traditional landscape and protecting biodiversity. The desertion of these relics of forest ecosystems, remnants of past natural refugee of regional flora and fauna, results the changes in the local environment, ecology, edaphology, climate and bio wealth and ultimately balance between biotic and abiotic elements of life supporting system in traditional landscape of Kerala.

6. Future Scope

Protection of environment and life supporting systems are interwoven with the conservation and protection of nature and natural resources. The Sacred Groves of Kerala represent this embracing concept and practice of traditional way of *in-situ* conservation of natural landscape. The Sacred Groves of Kerala is considered to be self generating and self sustaining ecosystem in the midst of modern urban environment communities. Hence, these ecosystems are also being influence the local climate by creating the conducive microclimate and protecting biotic and abiotic equilibrium. So the study enlightens the importance of the future events of conservation and management, traditional way of nature protection.

Author Profile

M. Rajendraprasad acquired his M.Sc. (Botany), M.A (English Language and Literature), Ph.D. (Botany) from University of Kerala, India and M.B.A from Indira Gandhi National Open University, New Delhi, India. Presently working as Senior Scientist, Jawaharlal Nehru Tropical Botanic Garden & Research Institute, Kerala. Former Senator of Kerala University is presently holding the position of P.G Board of Studies (Botany) member. Also served as recognized discussion panelist of Doordarshan Kendra, Thiruvananthapuram on Environmental issues. Author of Four books in scientific and environment issues.

T. Shaju received M.Sc. (Botany) from University of Kerala and Ph.D (Botany) from University of Calicut, Kerala. Presently working as Scientist, Jawaharlal Nehru Tropical Botanic Garden & Research Institute, Kerala. Taxonomist and Environmentalist, good in scientific illustrations. Co-author of One book.

G. Thulasidas graduate in Botany from University of Kerala. Presently working as Technical Officer, Jawaharlal Nehru Tropical Botanic Garden & Research Institute, Kerala. Expertised in field exploration trips, Garden Management and Landscapes.
