Abstract: Ultrasonic velocity, density and viscosity have been measured experimentally in binary mixture of ethanol and tannic acid at different temperature 298, 303, 308, 313K for the frequency 2MHz. The thermodynamic and acoustical studies clarify the nature of interaction between binary solutions, acoustical parameter such as characteristics of acoustic impedance(ζ), adiabatic compressibility(βa), relaxation time(τ) are calculated for these solution at different concentration to study solute solvent interaction. The variation in ultrasonic velocity and other parameters play a significant role in understanding solute-solvent interaction between the constituent molecules. The variation of ultrasonic velocity, density, viscosity, relaxation time and acoustic impedance indicate the presence of strong intermolecular interaction between the components of constituents’ molecules. Increase in velocity and decrease in adiabatic compressibility shows strong association and dipole- dipole interaction in the constituents’ molecules.

Keywords: adiabatic compressibility, viscosity, relaxation time, tannic acid

1. Introduction

The study of intermolecular interaction plays an important role in the development of molecular sciences. A large number of studies have been made on the molecular interaction in liquid systems by various physical methods like infrared [1, 2], Raman effect [3, 4], Nuclear Magnetic resonance, Dielectric constant [5], ultraviolet [6] and ultrasonic method [7, 8]. In recent years ultrasonic technique has become a powerful tool in providing information regarding the molecular behavior of liquids and solids owing to its ability of Characterizing physiochemical behavior of the medium. Studies and practical interest has been stimulated by investigation of organic liquids by ultrasonic measurements. Studies involving density & viscosity measurements are important for revelation of ion-solvent, ion-ion & solvent-solvent interaction in mixed solvent systems. The ultrasonic studies in binary liquids are essential for utilizing them in medical technology. Therefore it was thought worthwhile to understand ultrasonic study on some binary liquids & their mixtures [9-10]. Ultrasonic parameters are extensively being used to study molecular interaction in pure liquids, binary mixtures & ionic interaction [14-15] in single & mixed solution of tannins. Tannic acid is not a single constituent but a type of hydrolysable tannin that contain several units of Gallic or ellagic acid esterifies with glucose -OH to produce complex tannin compounds [16].

Here the attempts have been made for experimental investigations of derived parameters such as the ultrasonic velocity, adiabatic compressibility (βa), density, and viscosity of pure binary liquid tannic acid in ethanol at various molar concentrations in the range of 0.1mol to 0.09mol. The ultrasound frequency used was 2MHz at 298K, 303K and 308K. Adiabatic compressibility has been calculated from the ultrasonic velocity (u) and density (ρ) of the medium using the equation as

\[ β_a = \frac{1}{u^2} \rho \text{kg}^{-1}\text{ms}^2 \] ……… (1)

It is a measure of solvent-solute chemical interaction and the point of reference for the molecular orientation. We have also calculated intermolecular free length as

\[ L_f = K_T(β_a)^{1/2} \text{m} \] ………… (2)

Where \( K_T \) is Jacobson's constant.

Beyer and Letcher considered the case of plane harmonic wave & obtained a relation for acoustic impedance (Z) as

\[ Z = ρu \] …………… (3)

2. Materials and Methods

The liquid mixture of various concentrations in mole fraction was prepared by taking AR grade chemicals. The study was carried out for the temperatures 298K, 303K and 308K at fixed frequency 2MHz. The temperature of the liquid mixture was kept constant within an accuracy of ±0.1°C by using thermostat U-10. The experimental temperature was maintained constant by circulating water with the help of thermostatic water bath. Viscosity measurements were taken using Ostwald's viscometer with an accuracy of ±0.1Kg/m². The flow of time was measured by a digital stop watch capable of registering time accurate to ±0.1sec. An average of three sets of flow of time for each solution was taken for the purpose of calculation of viscosity. The density of the solution was determined accurately using 10 ml specific gravity bottle and electronic balance and accuracy in the density measurement is ±1x10⁻³ gm/cm³. An average of triple measurements was taken into account.

Ultrasonic velocity has been measured by Multi frequency interferometer (Mittal enterprises, M-83, New Delhi) operating at a frequency range 1MHz to 10MHz with an accuracy of ±0.01 m/s. The source of ultrasonic waves was a quartz crystal excited by a radio frequency oscillator. The cell was filled with desired solution and water at constant temperature was circulated in the outer jacket.
3. Results and Discussion

Figure 1: Variation of Ultrasonic Velocity versus molar concentration at different temperature

Figure 2: Variation of Density versus molar concentration at different temperature

Figure 3: Variation of Adiabatic Compressibility versus molar concentration at different temperature

Figure 4: Variation of Viscosity versus molar concentration at different temperature

Figure 5: Variation of Relaxation Time versus molar concentration at different temperature

Figure 6: Variation of Acoustic Impedance versus molar concentration at different temperatures
It is evident from fig.(6) that the acoustic impedance increases with decrease in temperature and increase in concentration of solution. The increase of acoustic impedance with concentration is due to the effective solute-solvent interactions.

It is observed that in fig.(7) that free length decreases with increase of mole fraction of the solute in system. This may lead to the presence of specific molecular interaction between the molecules of the liquid mixture. Intermolecular free length which is the distance between the surfaces of the neighboring molecules. Generally, when the ultrasonic velocity increases, the value of free length decreases. The decrease in intermolecular free length indicates the interaction between the solute and solvent molecules due to which the structural arrangement in the neighborhood of constituent ions or molecules gets affected considerably Decrease in intermolecular free length in system leads to positive deviation in sound velocity and negative deviation in compressibility. This indicates that the molecules are nearer in the system.

4. Conclusions

1) Increase in ultrasonic velocity with increase in molar concentration in this binary liquid system is due to molecular aggregation between the constituents molecules.
2) Nonlinear variation of thermo acoustics parameters with molar concentration shows the strong intermolecular interactions between the constituent molecules. Decrease in adiabatic compressibility and increase in acoustic impedance with increase in molar concentration is due to association in the constituent molecules.
3) The nonlinear variation of thermo acoustic parameters with molar concentration provides useful information about nature of intermolecular forces existing in binary liquid mixtures.
