Abstract: Adherence of soil in excavator buckets reduces their intake capacity. The methods used to remove this adhered soil e.g. jerking, damages bucket teeth and actuators. Gradually buckets need frequent replacement which increases operator’s costs and downtime. So, an effective mechanism is necessary in bucket which can avoid its jerking and can increase bucket life by reducing its damage. This paper suggests a spring-plunger mechanism connected to soil ejecting plate which is assembled in the bucket itself. The mechanism works with the curling and uncurling operation of the bucket. For this a prototype is made with CAD module, necessary theoretical calculations are done and model is validated with the FEA tool. Implementing this mechanism in the existing buckets will definitely reduce their jerking to significant level. Also the efficiency and life of bucket will increase to great extent.

Keywords: excavator, bucket, adhered, soil.

1. Introduction

Although excavators are used mostly for construction purpose, they have various other applications also like digging and maintenance of rivers, canals, ponds, drainages, etc. Excavators used in such operations have longer arms so as to achieve greater area of approach. They are used for distant digging operations. Such machines are called as ‘Long-Reach Excavators’. These have comparatively smaller capacity buckets and so soil compaction occurs more in them. While digging near riverside or canals, soil is mostly wet, forming lumps of about 1-1.5 kg. (See figure 1).

Figure 1: Bucket with adhered soil

Such lumps remain attached to inner-plates of bucket because of adhesion between soil and metal. M. Khan (2010), in his literature explains that soil adhesion increases with increase in moisture content [1]. These lumps are not easily removed during unloading stage of bucket. If this adhered soil is not removed, then it will reduce intake capacity of bucket during further digging operations. So, to remove this, mostly operators hit the bucket over its teeth against ground on some hard object like stone. This makes bucket teeth dull and sometimes they brake (See figure 2) [2].

Figure 2: Bucket with damaged teeth

Further due to such hitting (called as jerking), actuators of bucket damage. Operator’s maintenance cost and downtime increases and bucket needs earlier replacement. This reduces overall efficiency of bucket and machine (Vivek Ramsahai, 2011) [3].

This gives us the need for design and development of soil ejecting mechanism in buckets. Implementation of such mechanism will make bucket operations easy.

2. Literature Survey

Researchers have studied on this concept and developed some mechanisms [4]. Some of them are as below:
2.1 Excavator Bucket with Soil Ejector

George W. King (2004), suggested this mechanism. See figure 3 [5].

Here movable back surface of the bucket defines the loading and unloading stages as shown. This movable surface is the soil ejecting plate here which is supported with bolt and spring arrangement. When it gets actuated with the actuating member, it removes soil by moving in between the front and back positions (see figure 4) [5]. When rod attached to ejecting plate gets locked at a certain position, the plate moves forward and so the dirt is removed.

2.2 Self Cleaning Bucket

Daniel Ammons (2007) suggested this mechanism. See figure 5 [6]:

Here bucket is accompanied with ejecting plate whose one part is fixed with bolts and other part is hinged and the swinging one. One end of rope is attached to swinging part with the coupler and other end is fixed on arm with bolts. When rope tightens with the movement of arm, ejecting plate comes out and mud attached to it gets removed. Stopper is provided to control movement of ejecting plate (see figure 6) [6].

2.3 Bucket with Soil Ejecting Plate as Wiper

Gene Klager (2001), suggested this mechanism. See figure 7 [7].

Here, soil ejecting plate in the shape of wiper works with the fork attached to it as shown. Locking position of fork, moves wiper from back end to front position and so, the purpose is achieved (see figure 8) [7].
3. Spring-Plunger Mechanism

3.1 Concept

Excavator bucket has two side plates and one curved plate. This mechanism consists of a soil ejecting plate in the shape of bucket’s curved plate (see figure 9).

The plate is supported with one hinged rod. This rod moves plate within bucket’s size. One bracket is made in bucket which is welded to bucket’s surface. Ejecting plate is connected with plunger and spring. Bracket in the bucket is provided for resting of spring. A pusher is welded on tipping link of arm about which bucket rotates during curling-uncurling operation. This pusher forces the plunger head during the unloading operation of bucket (see figure 10). Force applied by pusher should be greater enough so as to rotate plate. When pusher applies force on plunger head, spring of plunger compresses and ejecting plate rotates about the hinged rod. Due to this, end of ejecting plate will go on shearing the soil attached to bucket. And so, all the mud will be removed. Again, when bucket moves in loading or digging position, spring extends back and so, the ejecting plate moves back and remains attached to bucket. For this arrangement proper angle between pusher and head is maintained so as to actuate movement of plate on proper time.

3.2 CAD Model

CAD model is prepared on NX 8.5, which shows actual assembly for such attachment. Minimum changes are made in the existing bucket. It has only one hole for hinged rod on side plates and a cut on bucket’s surface for mounting the bracket in it. See figure 11.

Hinged rod is utilised so as to give support to ejecting plate. Ejecting plate thickness = 8 mm.
Mass of Mechanism = 90 Kg.
Bucket’s capacity = 1100 Kg.
Volume Consumed by Mechanism = 1.8 %
Mass added on Bucket because of mechanism = 13.4 %

3.3 Theoretical Calculations
**Force Required for Shearing Adhered Soil**

This is calculated from Mohr-Coulomb Equation:

\[ \tau = \alpha + \sigma \tan \mu \]  

Where, \( \tau \) is the shear stress required to eject adhered soil, \( \sigma \) is normal stress due to soil’s weight, \( \mu \) is external friction angle. Bowden and Tabor equation defines normal stress \( \sigma \) on friction plane as below (see table number 1 and 2):

\[ N = \sigma A_r \]  

Where, \( N \) is normal force due to soil’s weight, \( A_r \) is the real contact area between soil and metal.

**Table 1:** Calculation for weight of adhered soil

<table>
<thead>
<tr>
<th>Density of Wet Soil (( \rho ))</th>
<th>Volume of Soil (V) Considering c/s of Plate</th>
<th>Mass of Soil (m)</th>
<th>Weight of Soil (N)</th>
</tr>
</thead>
<tbody>
<tr>
<td>1905 kg/m(^3)</td>
<td>0.052 m(^3)</td>
<td>100 kg</td>
<td>1000 N</td>
</tr>
</tbody>
</table>

Calculating Normal Stress from equation (1).

**Table 2:** Calculation for Normal Stress

<table>
<thead>
<tr>
<th>Weight of Soil (N) = m \times 9.81</th>
<th>Contact Area (AR), Considering Inner Bucket Surfaces</th>
<th>Normal Stress (( \sigma )) = N / AR</th>
</tr>
</thead>
<tbody>
<tr>
<td>1000 N</td>
<td>1.65 m(^2)</td>
<td>606 N/m(^2)</td>
</tr>
</tbody>
</table>

Calculating Shear Stress from equation (2). See table number 3.

**Table 3:** Calculation of Shear Stress

<table>
<thead>
<tr>
<th>Adhesion Coefficient (( \alpha ))</th>
<th>Normal Stress (( \sigma ))</th>
<th>External Friction Angle (( \mu ))</th>
<th>Shear stress to avoid adhesion (( \tau )) = ( \alpha + \sigma \tan \mu )</th>
</tr>
</thead>
<tbody>
<tr>
<td>12020 N/m(^2)</td>
<td>606 N/m(^2)</td>
<td>23.5(^0)</td>
<td>12283 N/m(^2)</td>
</tr>
</tbody>
</table>

External Friction Angle (\( \mu \)) = 23.5\(^0\) [10].

(Shearing Force to be provided by Plate = \( \sigma \times \text{Area} \) to eject soil adhered of aroun 100 Kg. ) = 12283 \times 1.65 = 7444 N

Shearing Force on Plate-end = 7.4 KN (3)

**Force to be applied by Pusher**

All the force will be applied by pusher when the piston of bucket cylinder will be fully retracted. Force applied by pusher should be greater than force required for shearing adhered soil.

Force applied by bucket cylinder in retraction is 113 KN.

So, calculating the force on pusher from force triangle law as below (see figure 12):

\[ F_x = \cos (76.4) \times 113 \times 1000 = 26.5 \text{ KN} \]

\[ F_y = \sin (76.4) \times 113 \times 1000 = 109.8 \text{ KN} \]

**Figure 12:** Force during retraction of cylinder piston

The direction in figure gives the force during retraction of piston of bucket cylinder. Now, calculating the force on pusher as below (see figures 13, 14):

\[ F_x = \cos (76.4) \times 113 \times 1000 = 26.5 \text{ KN} \]

\[ F_y = \sin (76.4) \times 113 \times 1000 = 109.8 \text{ KN} \]

**Figure 13:** Force calculation

\[ F_{(\text{theoretical})} = 7.36 \text{ Tons} \]

So, around 7.36 Tons of force is to be applied by pusher.

From (3) & (4), it is clear that pusher force is greater than shearing force. So, theoretically mechanism is correct.
• **Spring Design**

Spring being attached to the plunger should be sufficiently stiff enough to absorb impact of pusher.

Load which spring has to carry during compression = mass of adhered soil + mass of plate + mass of hinged rod and spring itself with plunger.

Considering wet soil density as 1905 kg/m$^3$ [11]; And mass of adhered soil as 100 Kg., this load comes to be 3838 N.

See Figure 15.

So, Spring Force = 4000 N

![Figure 15: Spring Formula](image)

[D = Mean Coil Diameter = 62 mm
d = wire diameter = 10 mm
Number of active coils = 5
Deflection = 48 mm](image)

3.4 **Finite Element Analysis**

• **Validating Force on Pusher**

Calculation of force on pusher by applying force on cylinder in retraction as 113 KN (see figure 16):

This comes to be 7.5 Tons (see figure 17).

These are the suggested material for pusher (see table no. 4) and ejecting plate (see table no. 5).

![Figure 16: Applying force on cylinder as 113 KN](image)

![Figure 17: Force on Pusher as 7.5 Tons](image)

![Figure 18: Stress on Pusher](image)

<table>
<thead>
<tr>
<th>Table 4: Material for Pusher</th>
</tr>
</thead>
<tbody>
<tr>
<td>Material for Pusher</td>
</tr>
<tr>
<td>S355</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Table 5: Material for Plate</th>
</tr>
</thead>
<tbody>
<tr>
<td>Material for Plate</td>
</tr>
<tr>
<td>S275</td>
</tr>
</tbody>
</table>

Below Figure shows stresses on pusher when this much force is applied on it (see figure 18).

• **Validating Force on Bracket**

The same force applied by pusher, is applied on stud head and resulting effect is analyzed as under (see figure 19):
Above figures show that von-Mises stresses induced are within permissible limit (see figure 20). Also force on pusher is greater enough to shear the soil. Stress limit given while checking are well above prescribed values. Furthermore we can correct these by proper welding to give sufficient strength to bracket.

4. Conclusion

The design and analysis of the model shows the basic concept for development of such attachment. Implementation of such mechanism on actual bucket will reduce need for jerking. Also it will increase bucket capacity. The mechanism may be replicated on excavator bucket of any size. Furthermore it may be actuated hydraulically to improve its functioning.

5. Future Scope

Further validation and actual test field results are needed for this model to measure the ejection forces and to commercialize the product. In addition additional testing is required to check the feasibility of the attachment for larger excavators.
